## **BUFFALO APPLIES FOR EIGHT NEW URANIUM EXPLORATION TENEMENTS IN QUEENSLAND AUSTRALIA**

**Vancouver, B.C., May 2, 2006 – Buffalo Gold Ltd. (TSX-V: BUF.U)** is pleased to provide an update on Buffalo's uranium exploration portfolio.

Buffalo has filed applications to enable it to further increase exposure to the Uranium market by securing a 100% interest in eight new Uranium prospective tenements in Queensland, Australia.

The eight new licence applications cover more than 2200 km<sup>2</sup> with potential for Uranium and also Vanadium-Molybdenum deposits in the Eromanga Basin, Queensland. The primary target is a sediment-hosted uranium deposit hosted within Cretaceous stratigraphy of the Eromanga Basin. The style of deposit, which may be found within these licence applications, maybe similar to the Mulga Rock Uranium-Polymetallic (Ni, Co, V, Sc) Deposit in Western Australia where mineralisation is associated with carbonaceous material in a sedimentary basin.

The Cretaceous stratigraphy within Buffalo's licence applications also has potential to host large polymetallic Vanadium-Molybdenum deposits such as the Julia Creek deposit (owned by Intermin Resources Ltd). The Julia Creek Project area is known to host very large deposits of vanadium/molybdenum rich clays, which have resulted from weathering of organic (oil) shales, which underlie much of the area.

No known systematic previous exploration for uranium has been carried out in Buffalo's new area due to the limited availability of radiometrics data to guide previous uranium explorers coupled with a general lack of uranium exploration in the past 2 to 3 decades due to market conditions.

The licence applications were targeted using airborne geophysical data and geology. Ground was selected after interpretations revealed almost 200 kilometres of strike length of the prospective Cretaceous sedimentary package. Where modern radiometrics data is available over the sedimentary package, it has anomalous response within the uranium channel. Up to 10 'clusters' of high amplitude uranium anomalies, with individual anomalies having a strike length of over 2 kilometres, are evident in the available radiometrics data. Only about half of the prospective area is covered with modern radiometrics data.
