

Supersenzor

Directed Fast Neutron System for Landmine Confirmation

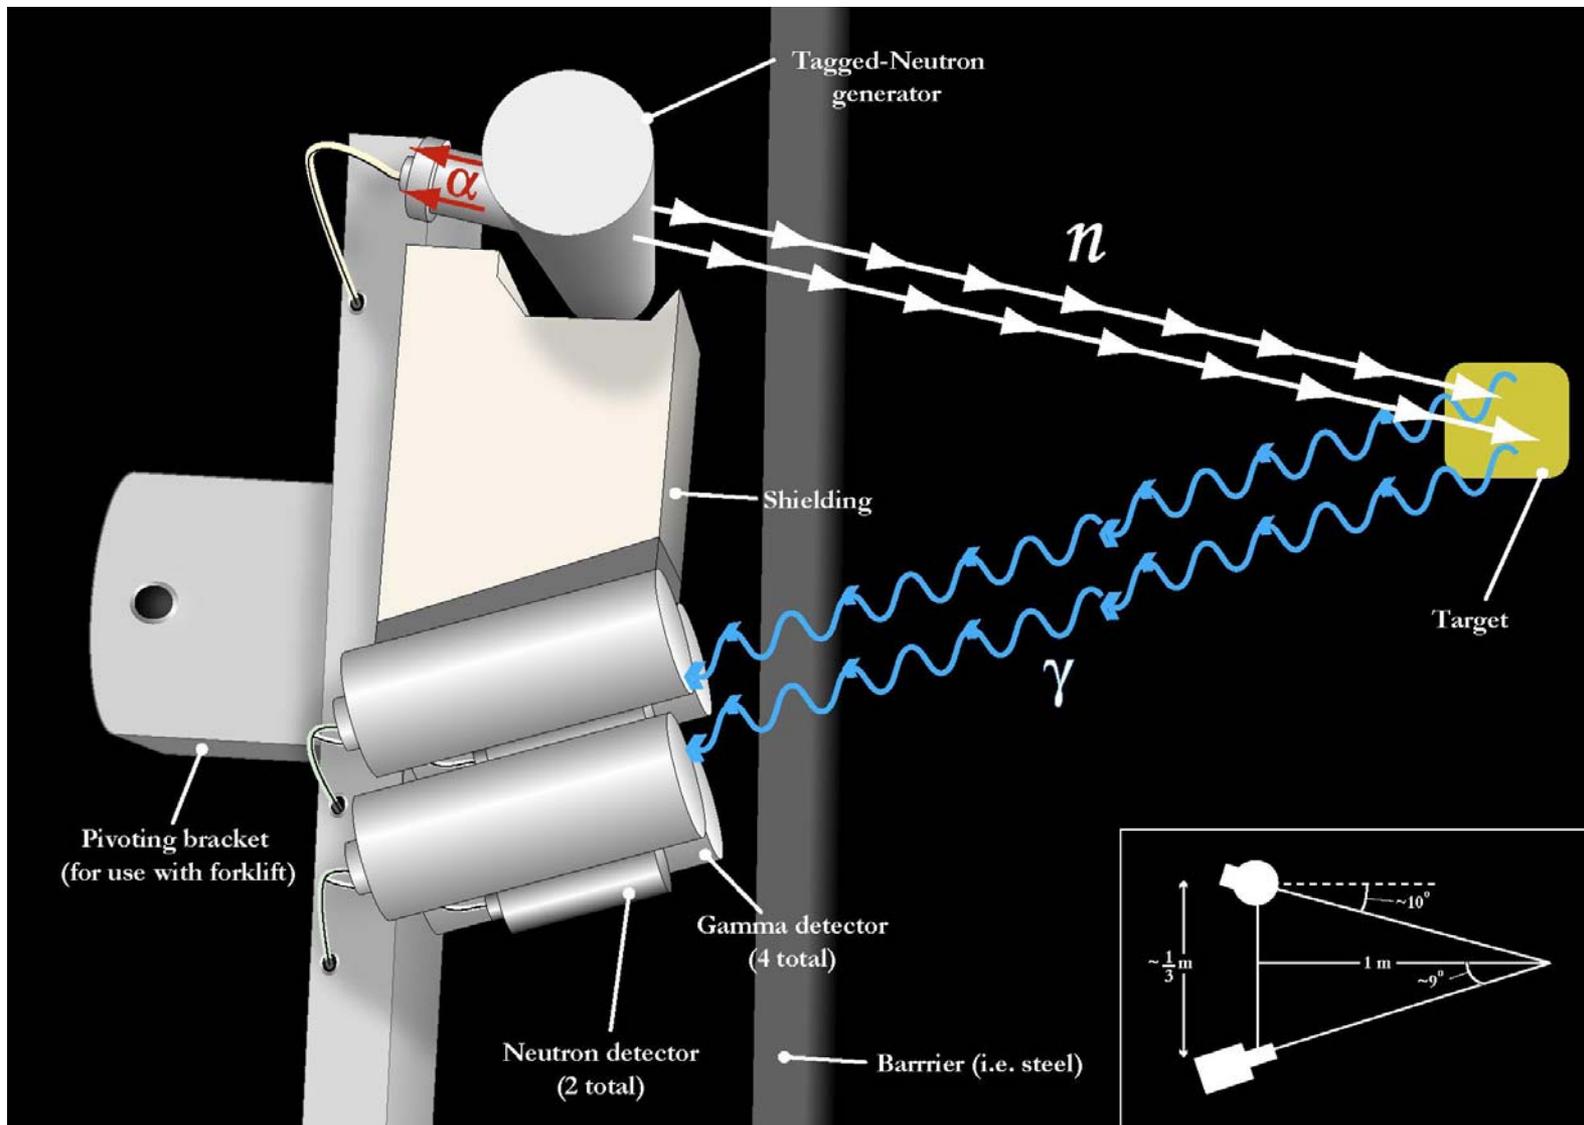

Bogdan C. Maglich, Tsuey-Fen Chuang, Christian Druey, Mu Young Lee and G.W. Kamin

HiEnergy Technologies, Irvine, CA, USA

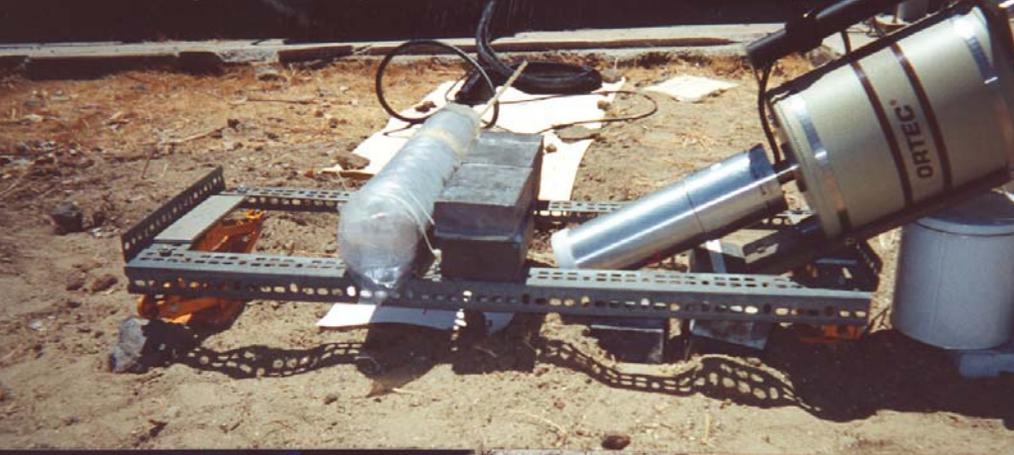

George Miller

University of California, Irvine, CA, USA

Supported in part by the U.S. Army's RDECOM Night Vision and Electronic Sensors Directorate through the Dept. of Defense Small Business Innovation Research program.

The key components of the Supersenzor system which utilizes directed fast neutrons to interrogate hidden targets

Under certain test conditions, Minisenzor (non-directional fast neutrons) is able to **identify** 5 kg of explosive simulant buried under 2" of soil.

Ongoing tests for US Army as part of HiEnergy's contract to develop an anti-tank land-mine confirmation sensor.

Ultimate device will incorporate a Supersenzor on a mobile platform.

Fast Neutron Analysis (FNA)

- Inelastic scattering of fast neutrons
- Measurement of prompt gamma rays

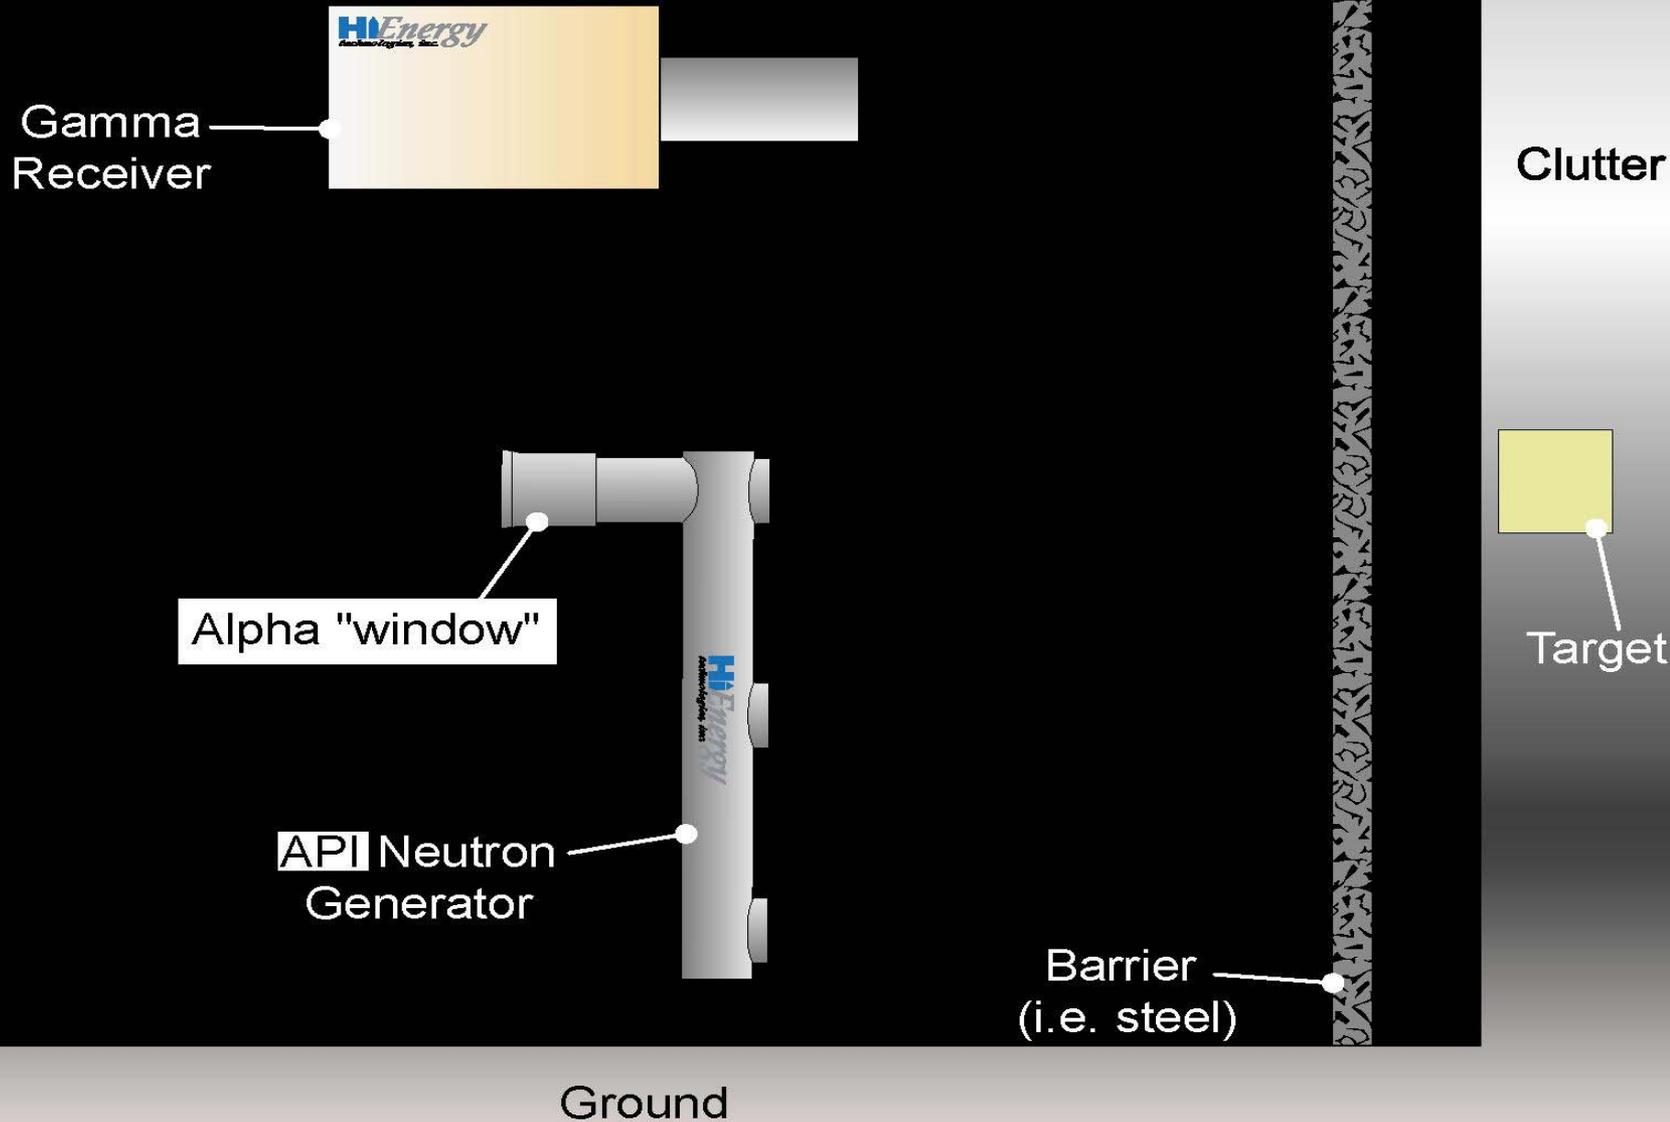

Associated Particle Imaging (API)

- Alpha-particle tagging of gamma rays
(a virtual “beam” of neutrons)

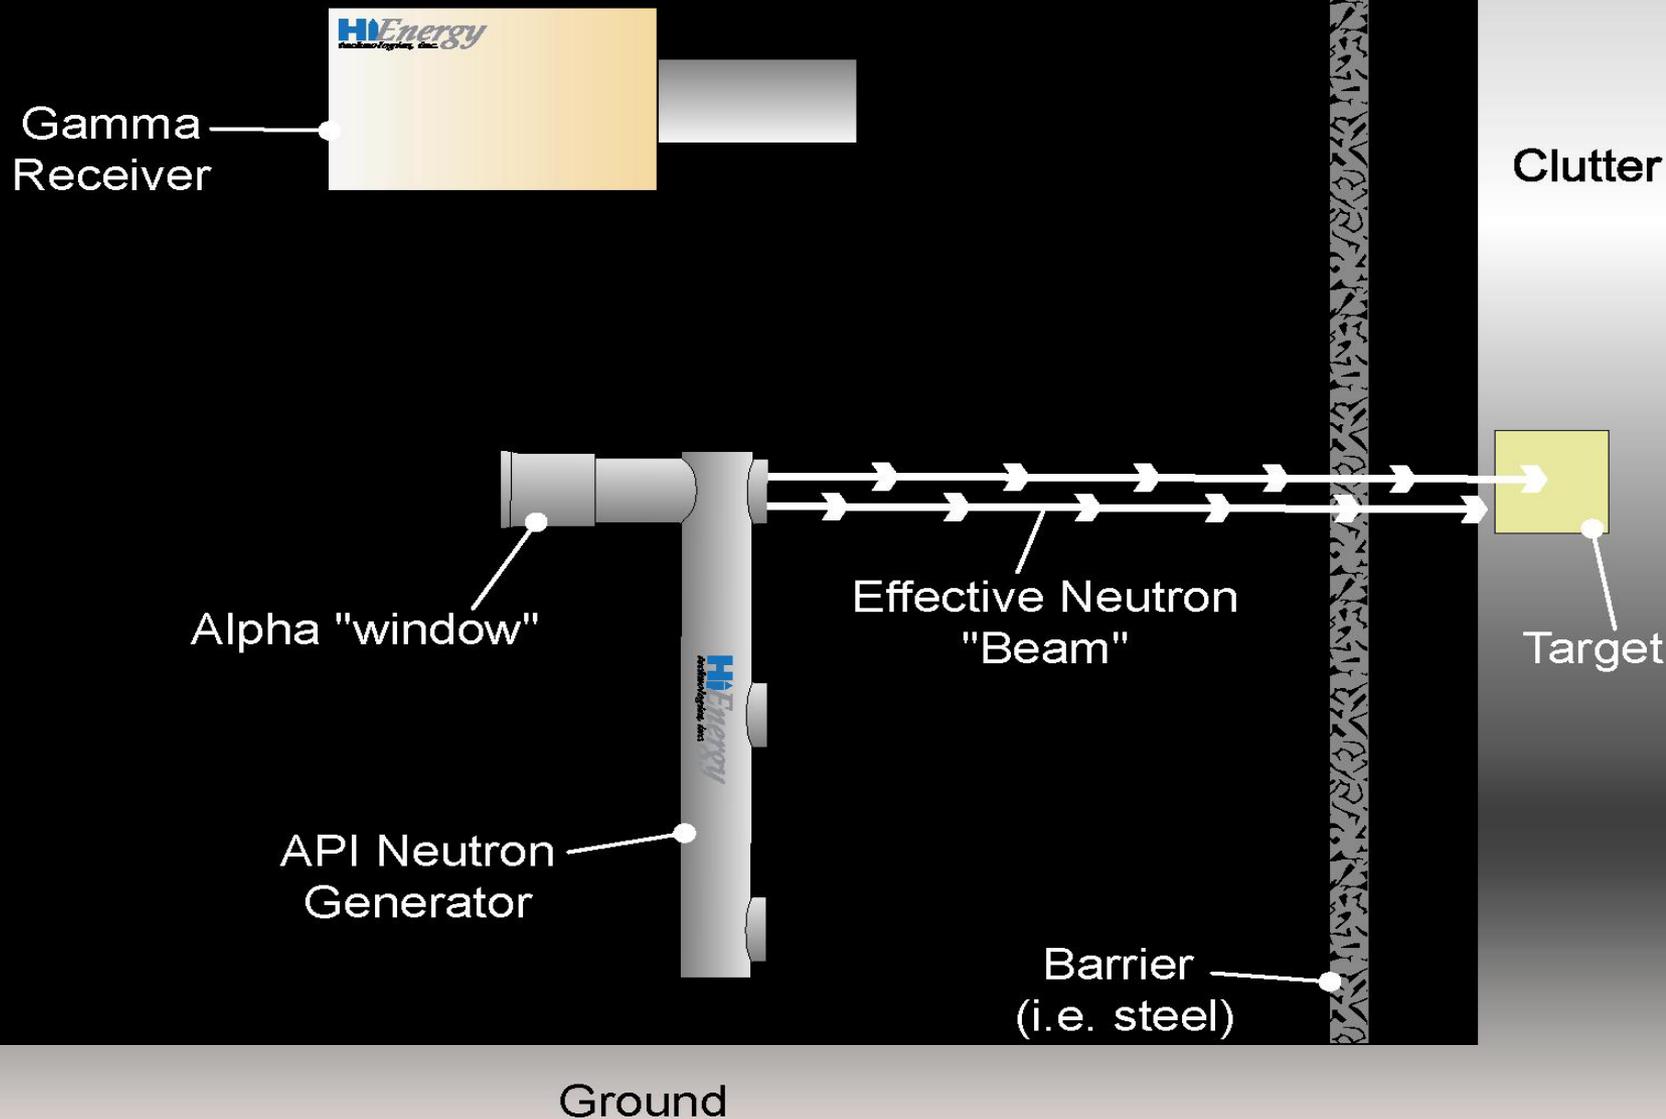

Improved API - Supersenzor

- Real-time
- Field deployable
- A truly **STOICHIOMETRIC** system

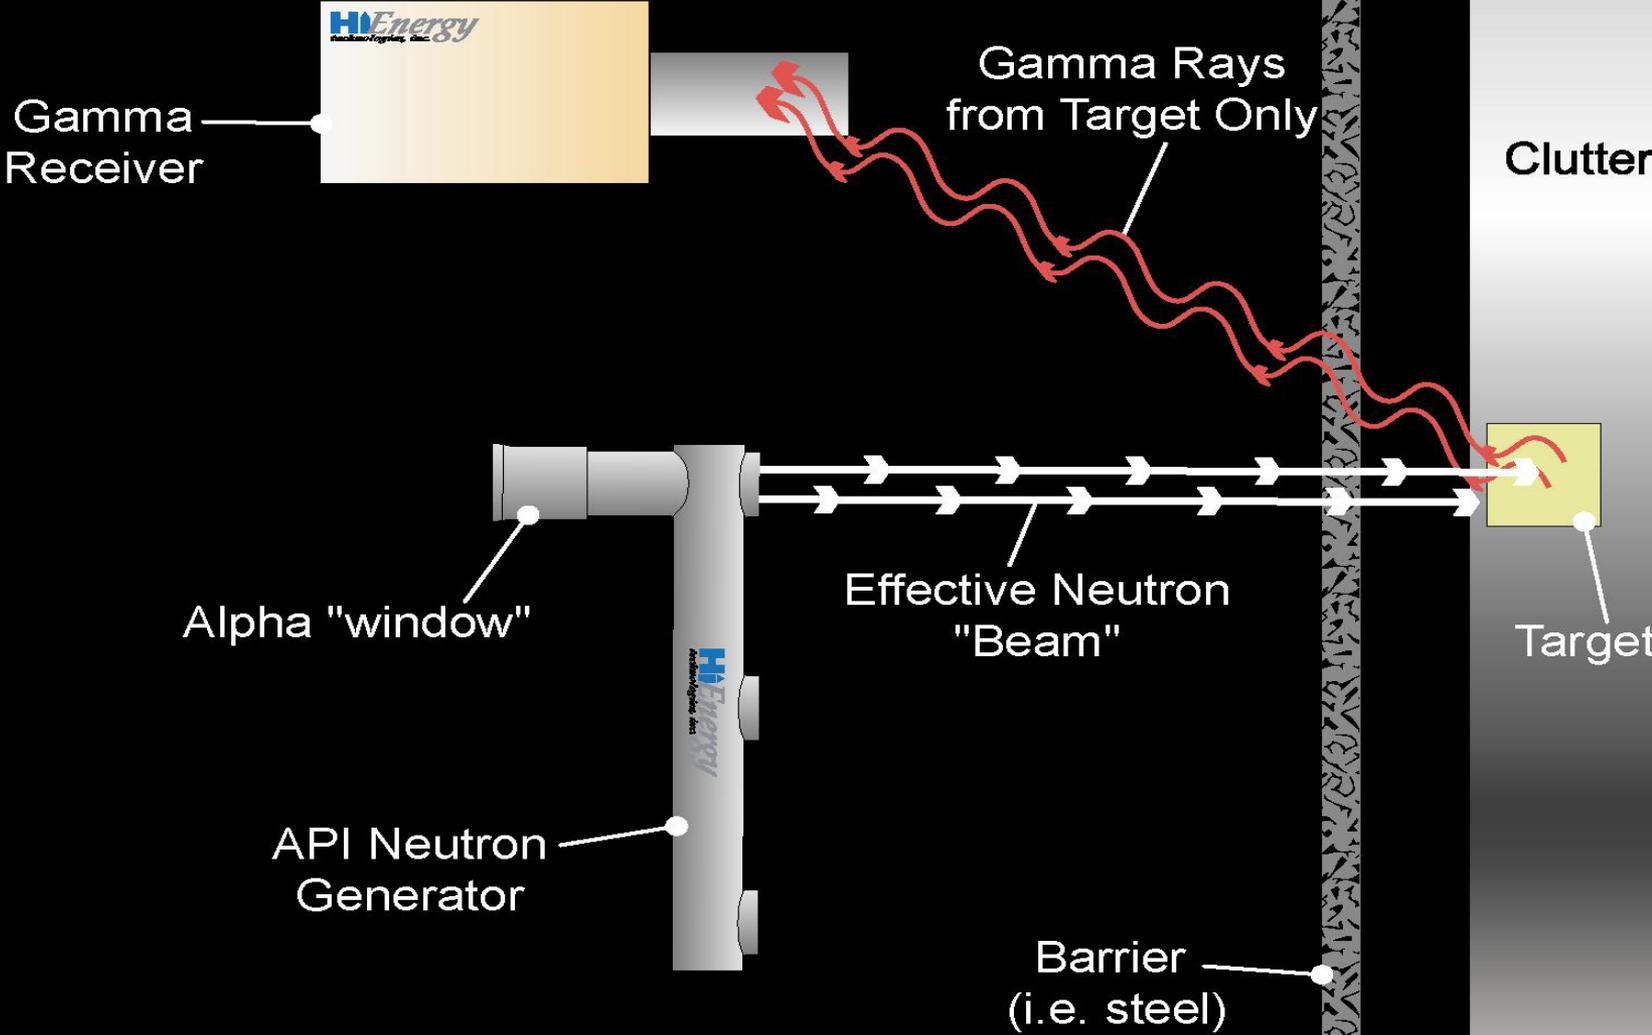

Supersenzor is directional - analyzes gamma rays from target only

Supersenzor is directional - analyzes gamma rays from target only

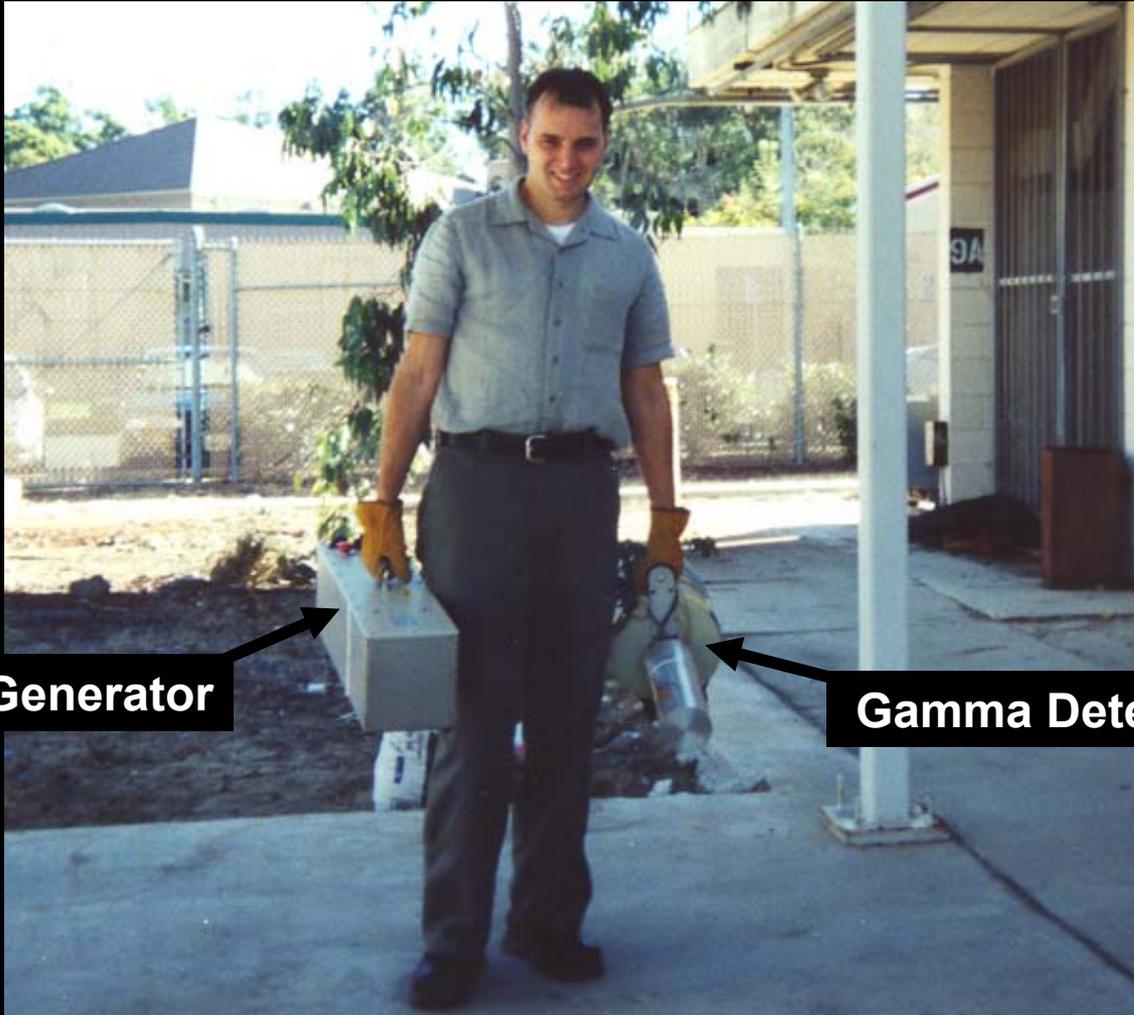

Supersenzor is directional - analyzes gamma rays from target only

Ground

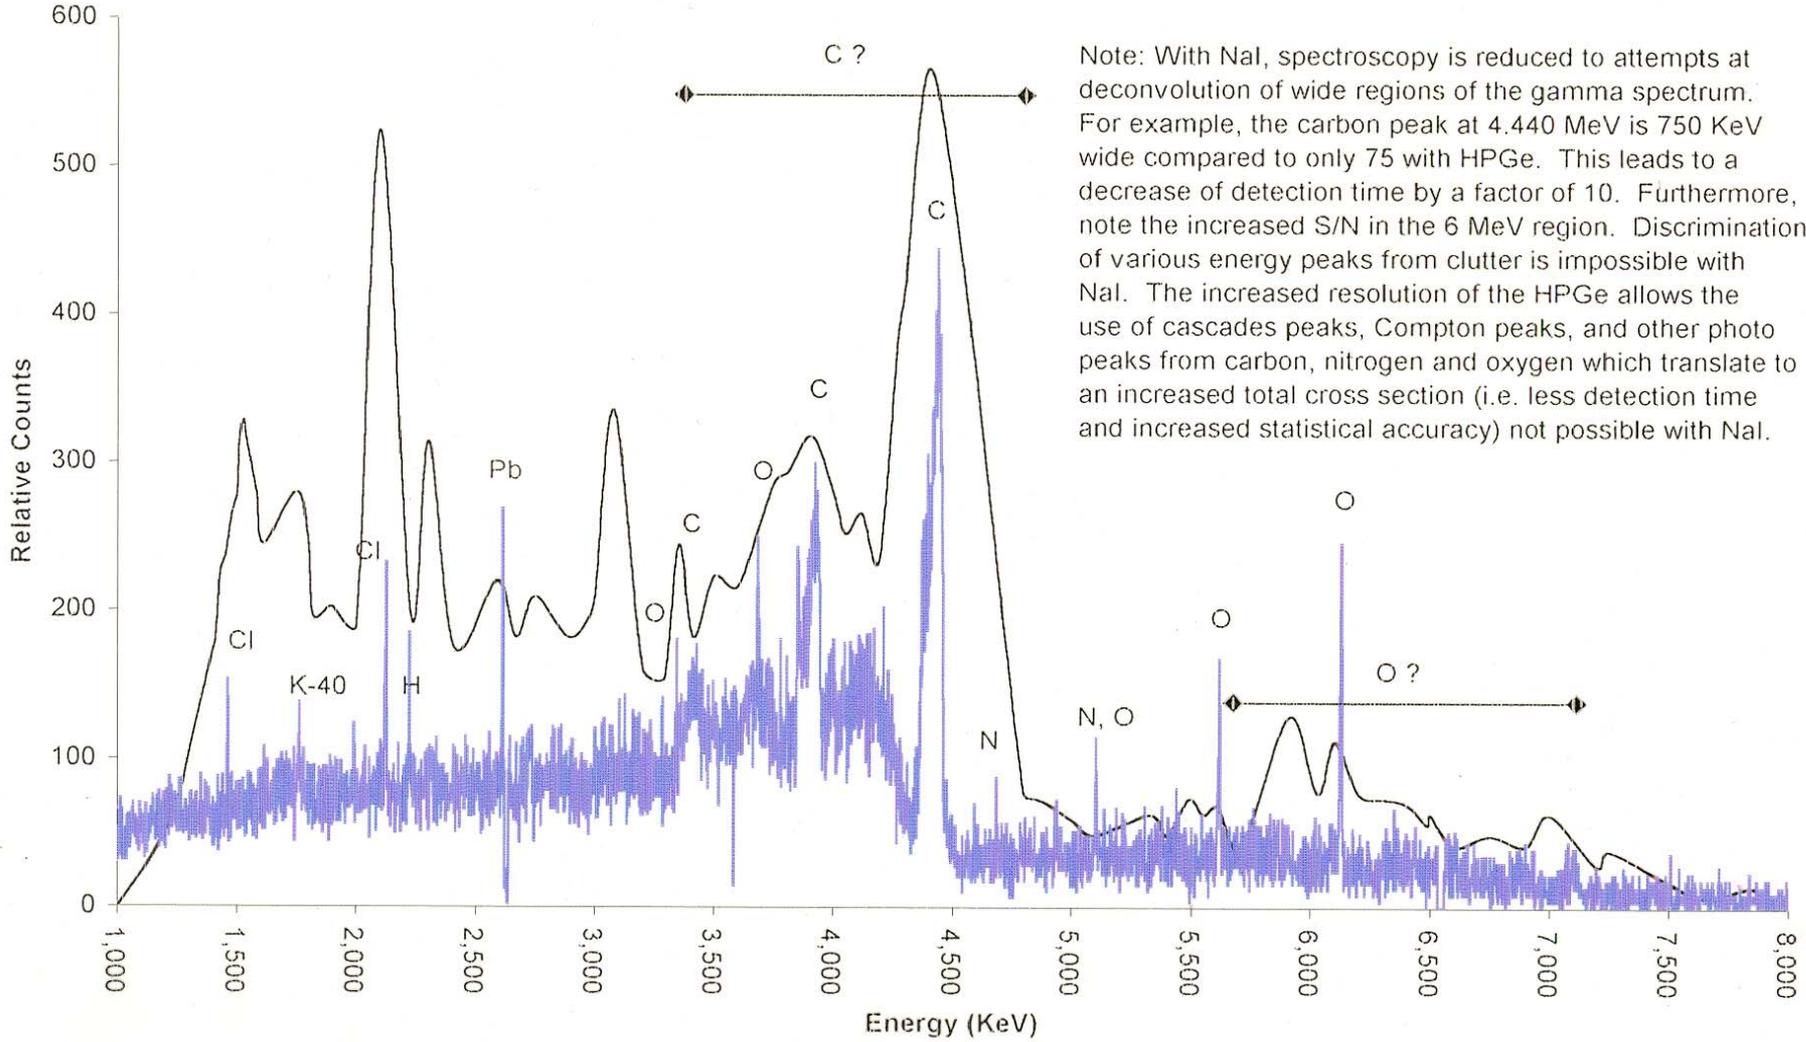

Portability

Neutron Generator

Gamma Detector

Spectra of cocaine hydrochloride with NaI (black contours) by Argonne National Laboratory versus HPGe (blue peaks) by HiEnergy

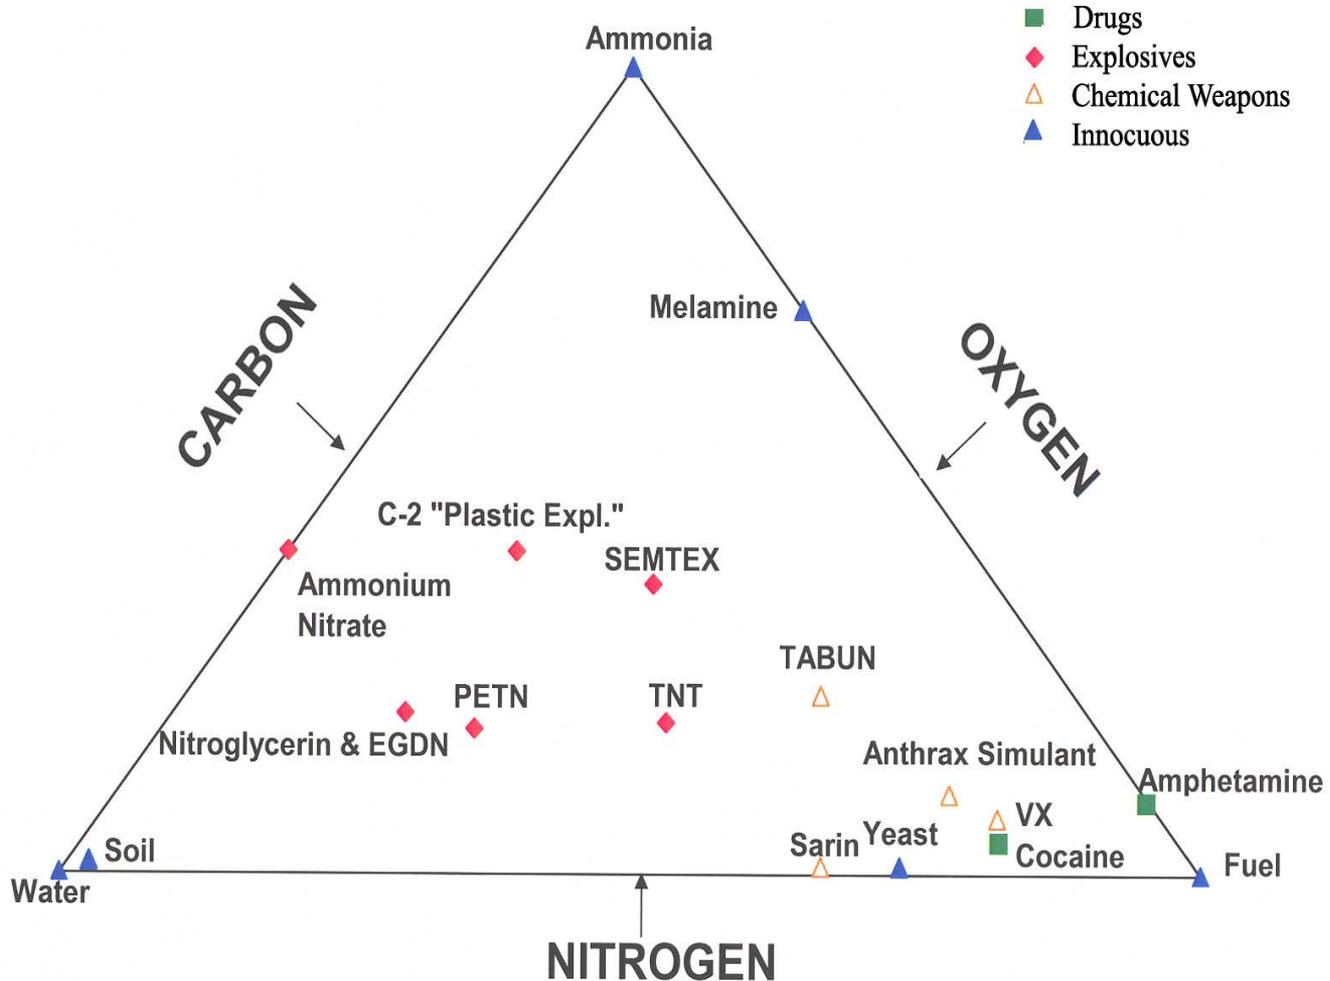

Note: With NaI, spectroscopy is reduced to attempts at deconvolution of wide regions of the gamma spectrum. For example, the carbon peak at 4.440 MeV is 750 KeV wide compared to only 75 with HPGe. This leads to a decrease of detection time by a factor of 10. Furthermore, note the increased S/N in the 6 MeV region. Discrimination of various energy peaks from clutter is impossible with NaI. The increased resolution of the HPGe allows the use of cascades peaks, Compton peaks, and other photo peaks from carbon, nitrogen and oxygen which translate to an increased total cross section (i.e. less detection time and increased statistical accuracy) not possible with NaI.

On-Line Stoichiometry

Graphical Display of 3-Element (C,N,O) Analysis

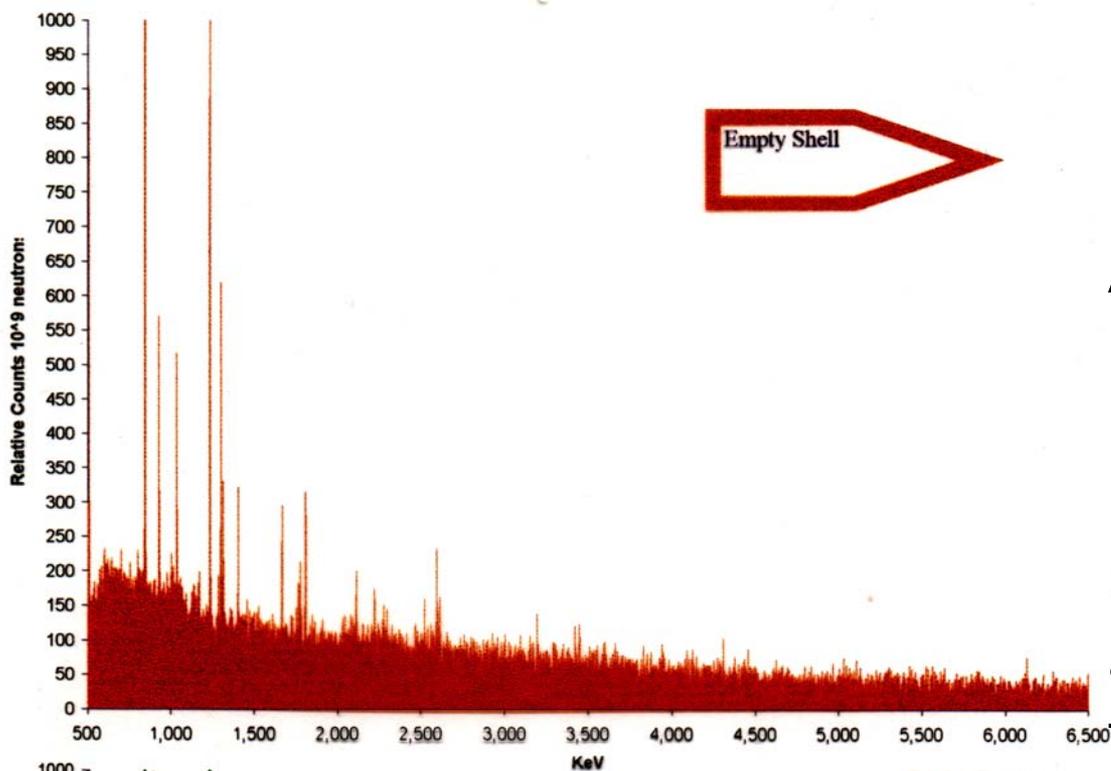

Reveals Empirical Chemical Formula

Validation of HiEnergy's systems

- Supersenzor in the laboratory
 - Cocaine hidden in rice (with US Customs)
 - Explosive filler in artillery shell
 - Distinguishing Anthrax from Yeast (DARPA)
- Minisenzor in the field
 - UXO filler* identification for US Navy
 - Land mine tests at UC Irvine

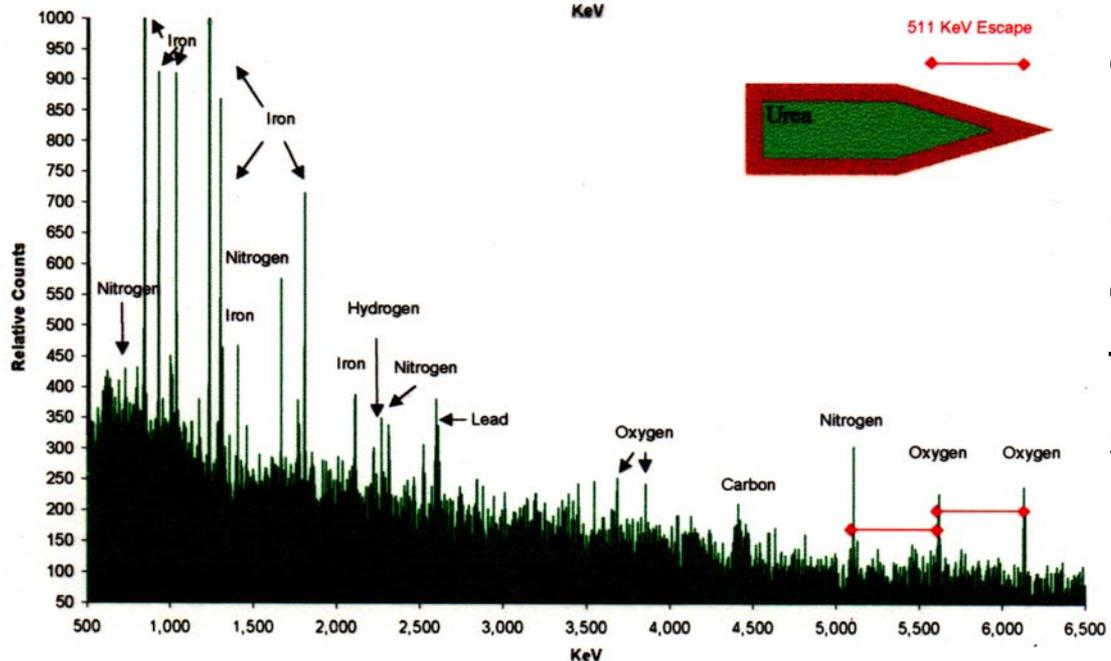

* actual explosive filler material – other tests and demonstrations were performed with suitable simulants

Empty Shell

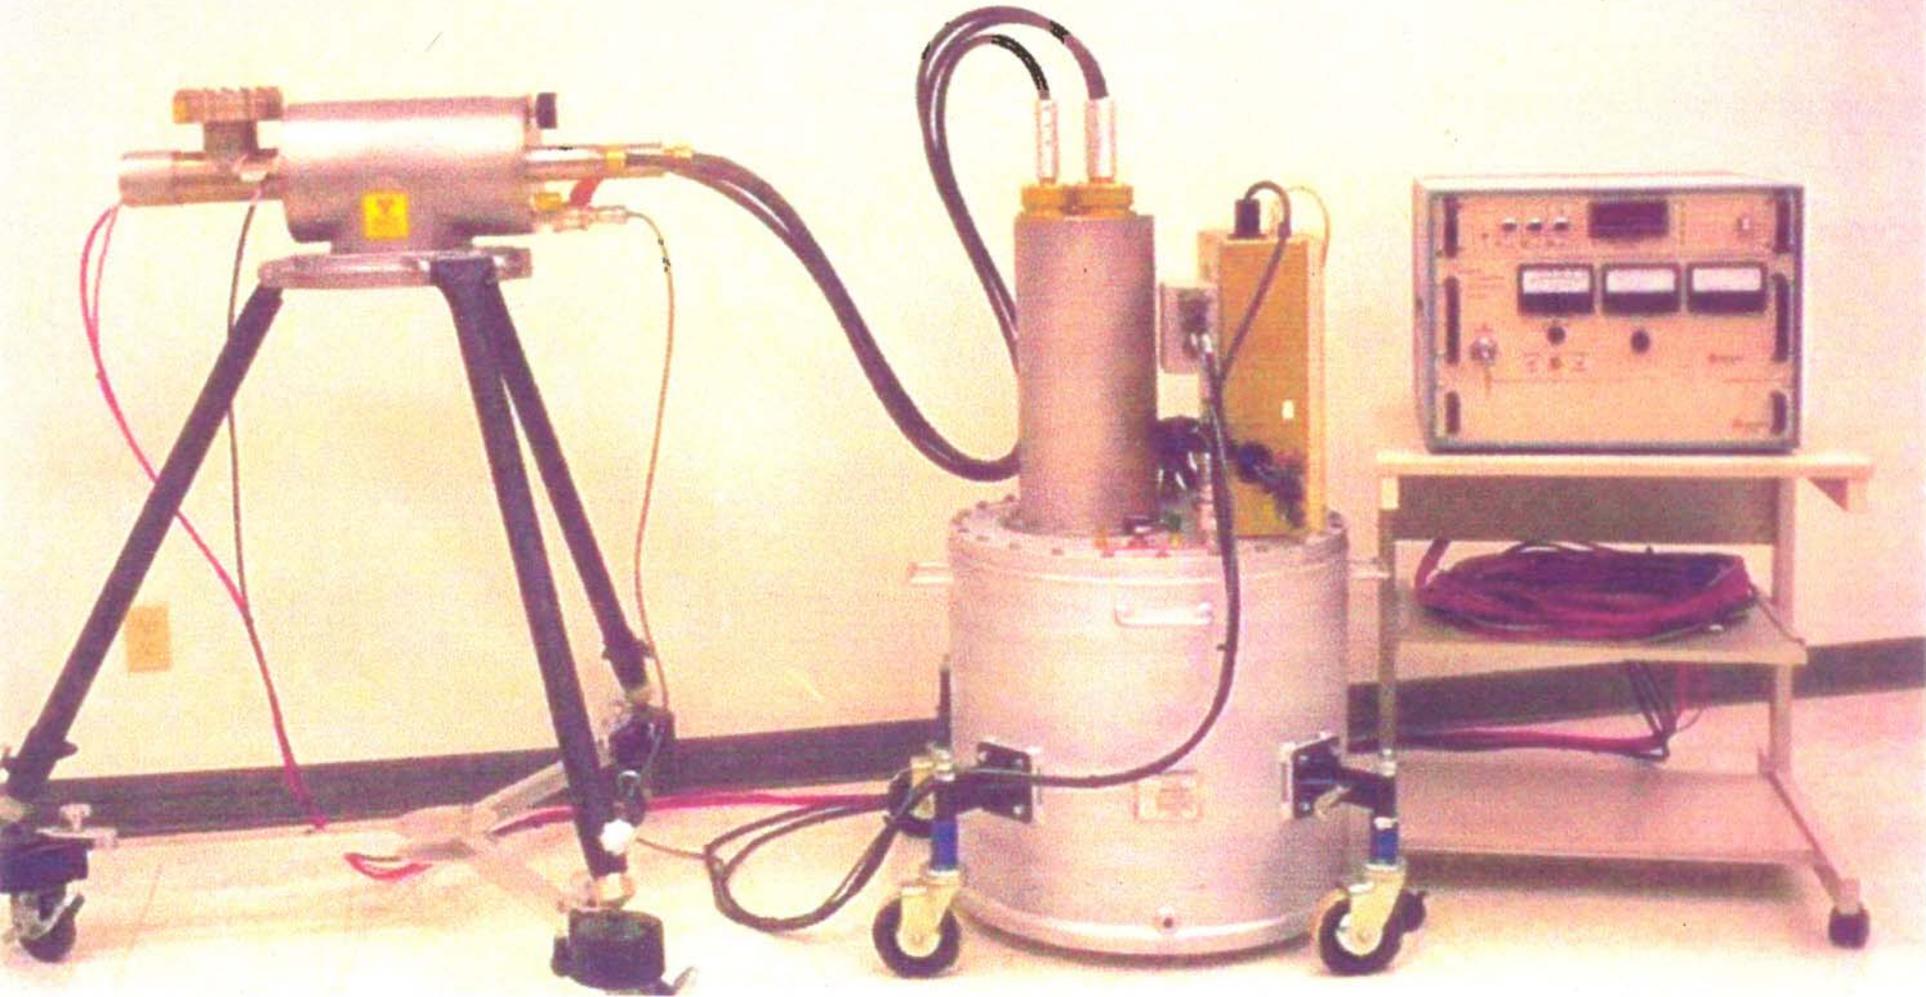

Artillery Shell Filler Test

Supersensor distinguishes an empty artillery shell from one containing an explosive simulant.

Urea

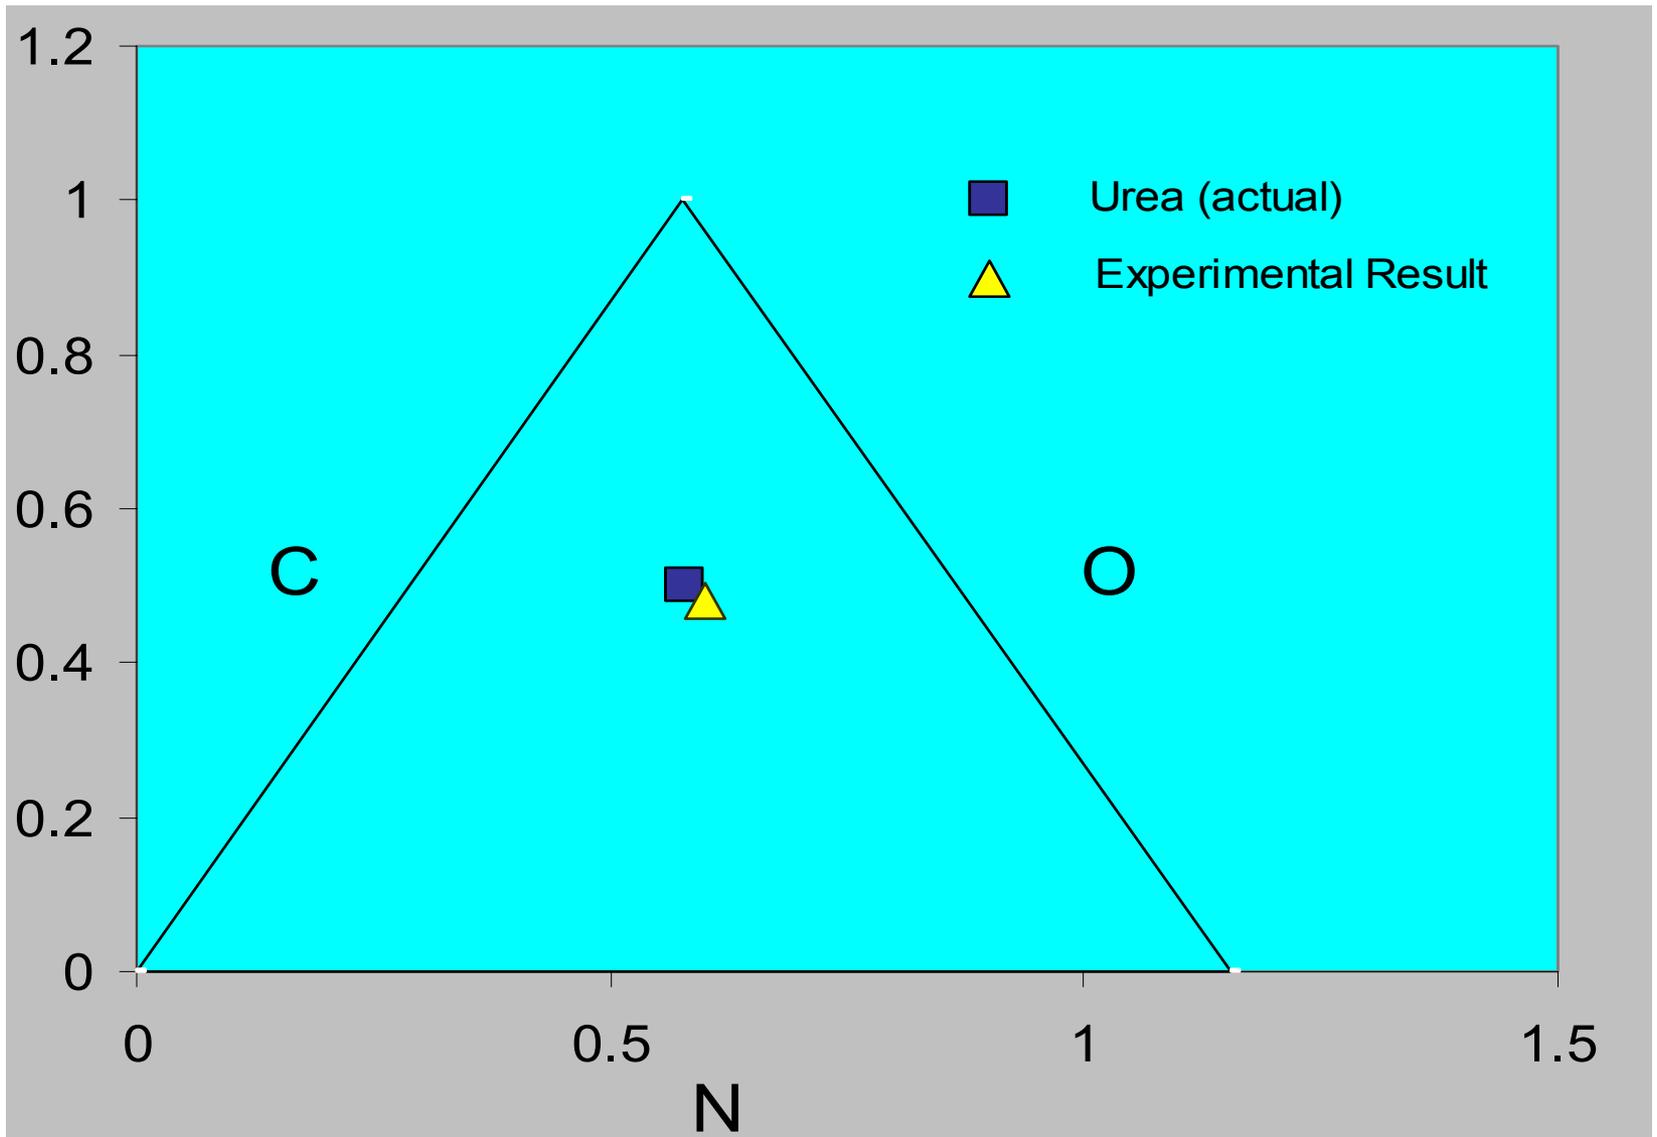

Supersensor correctly deciphers the chemical formula of the explosive simulant.

Non-portable API Neutron Generator
with 8 kW Power Supply

Artillery shell
suspended in air
with polyethylene
shielding And
HPGe gamma
ray detector

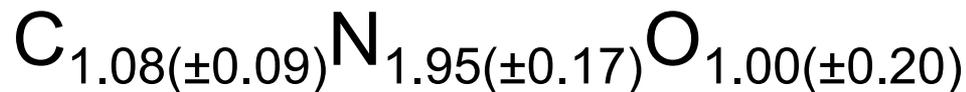

Graphical representation of results from Supersenzor interrogation of artillery shell.

Artillery Shell Filler Identification Test of Non-Portable API System

- 5 kg of explosive simulant (urea)
- Distance of 1 meter (in air)
- Actual formula:

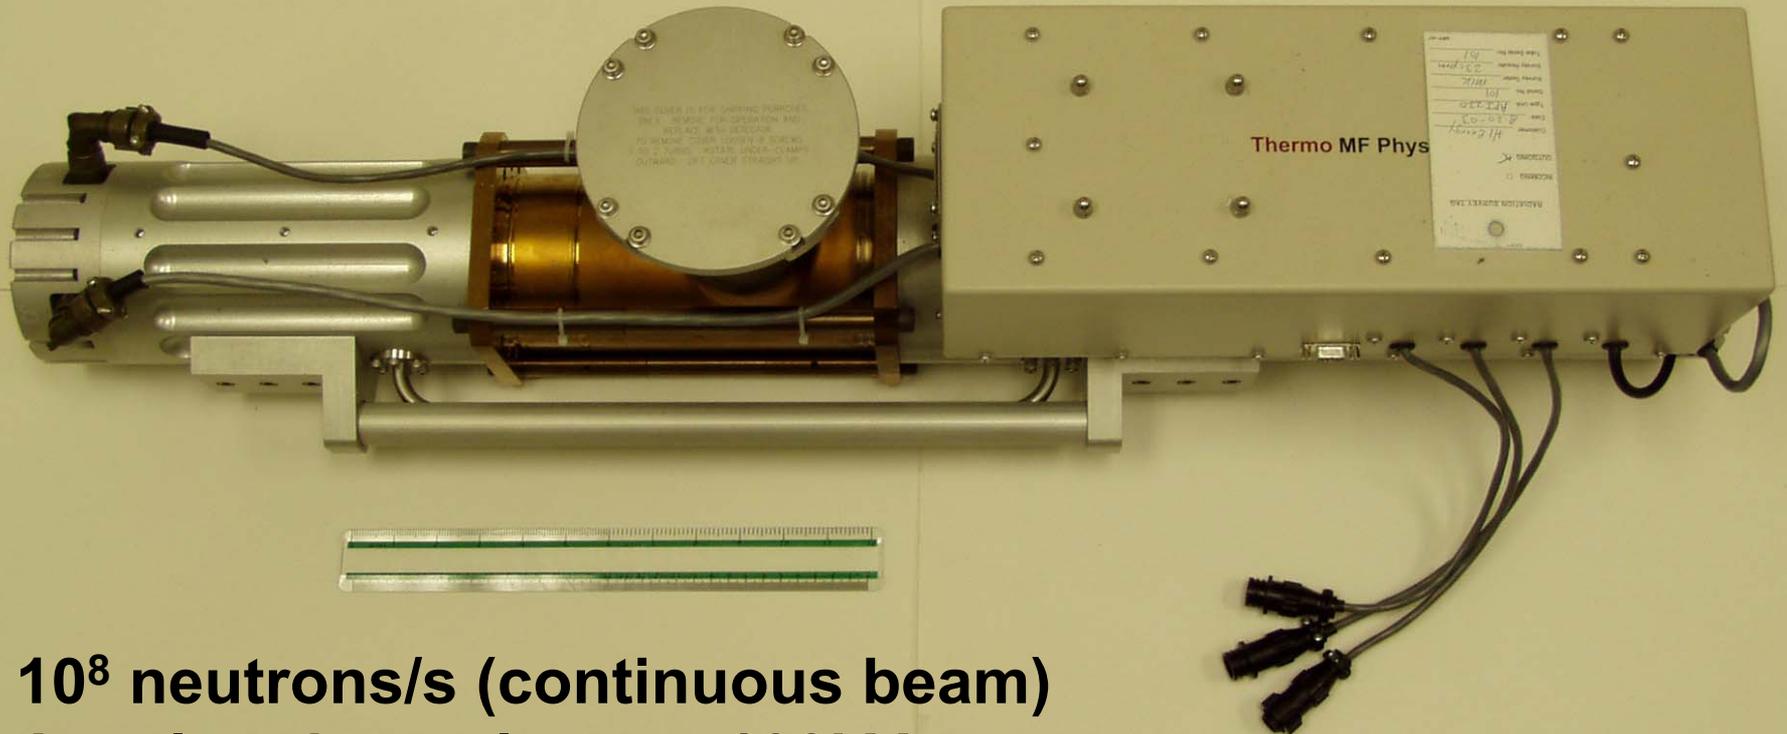

- Experimental results:

- Estimated detection speeds for portable
Supersenzor (5 kg in soil):

10 ~ 300 seconds (40x faster than above)

Portable API Neutron Generator

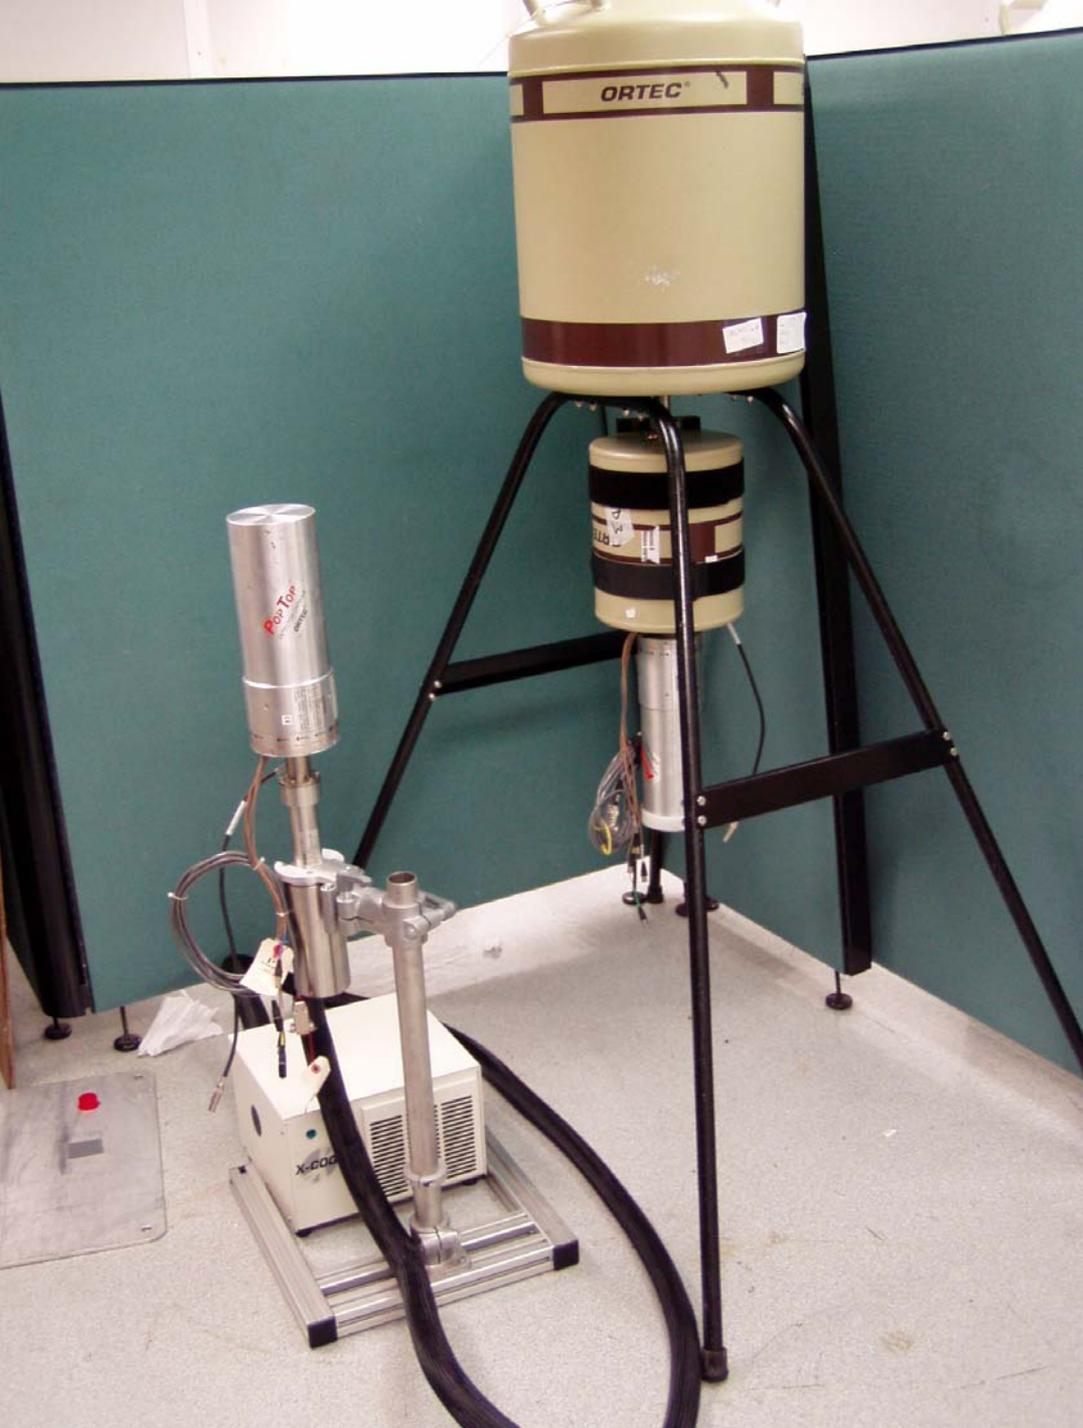

10^8 neutrons/s (continuous beam)

Accelerating voltage: <100kV

Mass (including HV power supply): 22 kg

Length: 1 m

Power: 75 Watts (24V DC)

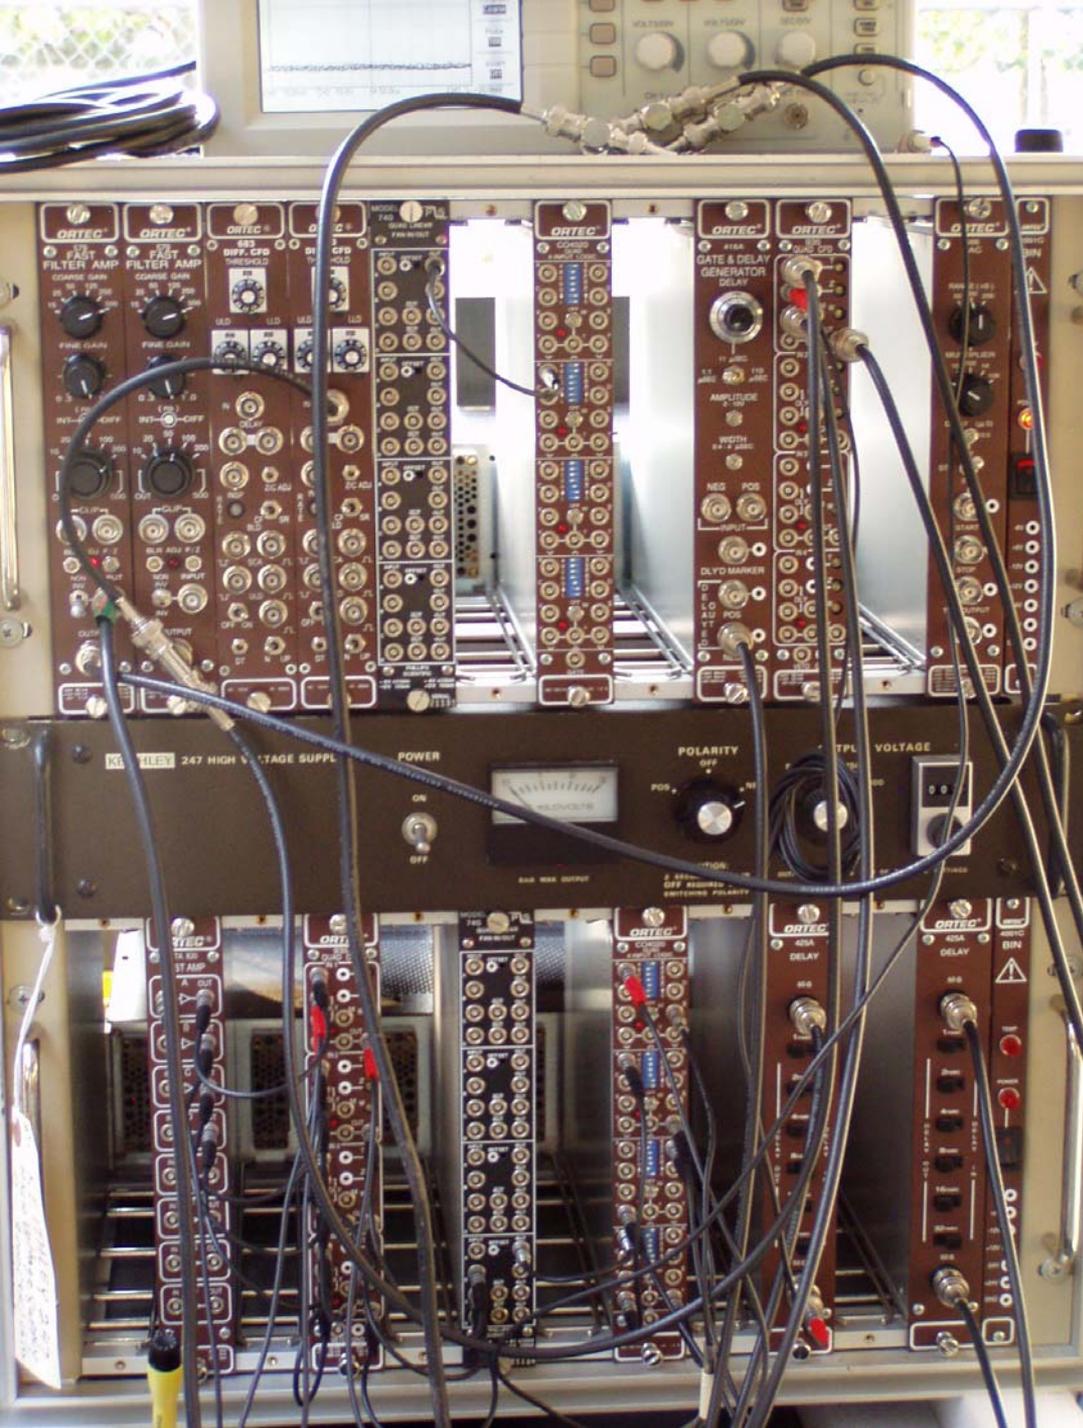

Electric Cooling of Detectors

First Generation:
One detector (<90% eff.)
300 Watts
Non-portable (shown)

Second Generation:
Up to 4 detectors
300 Watts
Portable (Fall 2003)

Third Generation
One detector
20 Watts

Electronics

Prototype:

Rack mounted NIM logic.

300 Watts

DSP for gamma-ray pulse height analysis.

Single-pixel (voxel).

Production:

Integrated logic and pulse analysis on a single low-power PC board with multi-voxel imaging capability.

Supersenzor

Ongoing Development

- First field tests of portable Supersenzor
- Robust data analysis algorithms
- System integration (software and/or hardware) with miniaturized electronics
- Faster detection times due to improved DSP
- Ruggedized and standardized HPGe detectors
- Elimination of liquid nitrogen cooling
- Multiple HPGe gamma ray detectors
- Multi-voxel, 3D chemical imaging capability
- Optimized radiation shielding for field use
- Remote-controlled vehicle platform
