1.0 SUMMARY

This report is a summary of the New Pass Project and was prepared at the request of Basil Pantages President of Consolidated Odyssey Explorations, John Leaske President of White Knight Resources, Ltd. as a technical report in support of the acquisition of the property. The New Pass Property is located in eastern Churchill County, Nevada approximately 190 kilometers east of Reno, Nevada. The Property is comprised of a total of 107 unpatented mining claims located on the western flank of the New Pass Range. The company has acquired the right to earn an interest in the property subject to a joint venture agreement with White Knight Resources, Ltd.

No known historical production, shafts, adits or prospect pits or other exploration work had been completed on the property prior to 1980. At that time, using stream sediment data developed by the NURE program, an arsenic stream sediment anomaly along the western side of the New Pass Range was investigated which led to the discovery of a large, outcropping jasperoid deposit. Surface samples of the jasperoid reportedly had an average assay value of 0.02 ounces per ton Au for the exposed mineralization. Since that time, the companies involved in the project have spent in total over US \$ 1,500,000 exploring the property.

Geological work done to date has shown that a thick section of Upper Paleozoic and Mesozoic sedimentary rocks, primarily calcareous rocks, dominate the New Pass Range. On the subject property, these rocks are separated from a Tertiary age volcanic sequence to the west by a major range bounding structural zone. This zone has also served as a locus for a large hydrothermal system, with the jasperoid having been deposited within this structural zone.

The hydrothermally – altered rocks extend for at least 2.5 miles along the range front fault, and for about 0.5 miles eastward into the New Pass Range. The western extent of the mineralized and altered area is buried beneath pediment alluvial cover. Felsic intrusive bodies, mainly dikes, crop out on the property. With the extensive mineralization and alteration on the property and the felsic intrusives, it is possible that an intrusive lies at depth.

During the recent visit to the New Pass property a total of 9 samples (Nos. 198859 through 1988198867) were taken from various locations on the property by the author. Two of the samples returned greater than 1 ppm gold and elevated concentrations of pathfinder elements.

Drilling completed by predecessor companies has identified a total Indicated Resource of about 3.37 million tons grading 0.042 ounces per ton Au at a cutoff grade of 0.02 ounces per ton Au. This resource is contained entirely within the jasperoid. 2.1 million tons of this material is oxide with a recovery of 75% to 77%. The balance is pyritic (1.27 million tons) with a recovery between 5% and 33%. The overlying Tertiary volcanics to the west of range bounding fault were considered to be post-mineralization by the companies working on the project. Consequently, the volcanics were never sampled, save for 2 drill holes sampled in 1992 which returned highly anomalous Au intervals. Also, the underlying altered rocks, primarily de-calcified limestones also have

not been extensively targeted for sampling. In addition, favorable north easterly trending faults which can be projected under the pediment have been mapped north and south of the main jasperoid body. Coincident geochemical anomalies for Au-Ag-As-Sb-Hg-Mo have been recognized along these structures.

Extensive geochemical surveys have been completed on the property by previous workers. These surveys primarily were factor analysis on rock chip and drill chip samples. While substantial geochemical analyses were completed, as far as can be determined from the available data, *no* geophysical surveys were completed on the New Pass Property

The gold mineralization associated with the jasperoid at New Pass has not been sufficiently defined or investigated within the known area of alteration, especially in the Tertiary volcanics and in the underlying de-calcified limestones.

The first year's work program is divided into two Phases. Phase I will consist of the assembly and recompilation of the existing data into a modern digital data base, which will allow the re-plotting and reinterpretation of the previous work. In addition detailed geological mapping and several geophysical surveys will be conducted including, an Air Magnetometer, an Induced Polarization – Resistivity and a Gravity survey. The Phase I program is estimated to cost US \$ 78,000.

Following the completion of the 1st Phase, Phase II will commence. Phase II will consist of drilling, both reverse circulation and diamond core. The estimated cost of Phase II is US \$ 172,500, making the total Year One expenditures US \$ 250,500.

2.0 INTRODUCTION AND TERMS OF REFERENCE

At the request of Basil Pantages, President of Consolidated Odyssey Explorations, Inc. ("Odyssey"), and John Leaske President of White Knight Resources, Ltd. Paul Pelke (The "Author"), was requested to prepare a technical evaluation report under the guidelines of National Instrument 43-101 on the New Pass Property located in eastern Churchill County, Nevada (Figures 1 & 2). The Technical report is to be submitted to the TSX Venture Exchange in support of Odyssey entering into a joint venture agreement with White Knight Resources on the New Pass Property.

Outside sources of information used in the completion of this report consist mainly of company reports on the New Pass Project. Several consultants' reports were also available. All of this data was examined at the White Knight Resources office in Reno, Nevada. No data in digital format was available, nor is there any historical data available in Mackay School of Mines files and the University of Nevada, Reno, since the area was discovered only in 1980. The only public domain information relevant to the New Pass Project are various general regional geological resumes.

Paul Pelke, the Author, conducted a field visit to the New Pass Property on October 12, 2004, for the purpose of examining the project site, collecting geological samples, assessing the geology and assessing the styles of mineralization and alteration on the property. A total of 9 surface samples were taken, mainly from the main jasperoid, and submitted to BSI Inspectorate for analysis. Sample descriptions and the analytical results are presented in Appendix II, and discussed in Section 9, Section 12, Section 13 and Section 14.

3.0 DISCLAIMER

The Author has reviewed and analyzed the data held by White Knight Resources in its Reno, Nevada office. This data consisted of a series of internal and consultant's reports containing information on the geology, mineralization, metallurgy and exploration activities. The reports were completed by NICOR Minerals, Westmont Mining, Consolidated Ramrod Gold / Quest and White Knight Gold (U.S.), Inc. The principal reports used are referenced in Section 21. Other information consisting of drill logs, various mylar, vellum and paper maps and some computer generated plots were also examined and some of that information is also used in the preparation of this report.

Specifically the mineralization cross sections used in Figure 6 were computer generated using Interdex software but no digital data of any kind was to be found in the files. Hard copies of two of the cross sections were scanned and redrafted. The colored histograms on the drill holes have been included, although the meaning of the color coding is not known, nor is the scale of the individual bars known (i.e., are they linear, logarithmic?). These cross sections were included only to demonstrate the geometry of the known mineralization, rather than to imply anything quantitative about the mineralization.

In 1988 and 1989, Westmont Mining retained Independent Mining Consultants of Tucson, Arizona to perform a computer based ore reserve calculation. The results of this exercise gave a total of 3.371 million tons that graded 0.042 ounces per ton Au, or a total of 142,000 contained ounces, after applying a cutoff of 0.02 ounces per ton Au. Included in this total is 2.1 million tons of oxide material with a recovery of 75% to 77% and 1.271 million tons of pyritic material with a recovery of between 5% to 33%. These numbers have been referred to in the various reports and internal memos as: "Reserves", "Geological Reserves", "Geological Resources" and "Resources". However, after examining the available data, including drill logs, assay logs, drill hole locations and density, metallurgical work completed and the nature of the mineralization and then applying the principles outlined in the "Australasian Code for Reporting of Mineral Resources and Ore Reserves" (The JORC Code) to this data, the term that is most appropriate for this deposit and which will be exclusively used in this report is "**Indicated Mineral Resource**" (IMR) or simply "**Indicated Resource**".

A complete listing of the claims comprising the New Pass Property is given in Appendix I. All of the claims listed are considered to be valid by the BLM, with the 2004 – 2005 claim maintenance fees having been paid

4.0 PROPERTY DESCRIPTION AND LOCATION

The New Pass property is located in eastern Churchill County, Nevada approximately 190 kilometers east of Reno, Nevada (Figures 1 & 2). The property consists of 107 unpatented lode mining claims covering approximately 2,140 acres (866 ha) along the western margin of the New Pass Range. The claims are located in Sections 5, 6, 7 & 8, Township 20 North, Range 40 East; Sections 25 & 36, Township 21 North, Range 39 East and Sections 29, 30, 31 & 32 Township 21 North, Range 40 East. A complete list of the claims is given in Appendix I. All of the claims listed are considered to be valid by the BLM, with the 2004 – 2005 claim maintenance fees having been paid

The property is accessed from Reno by following Interstate 80 east 30 miles to Fernley, and then east along Highway 50 through Fallon for 110 miles to the graded Edwards Valley Road. And then proceed 5 miles north to an unimproved road, and then 2.5 miles east south east to the center of the property.

The claims are unpatented lode mining claims, located on lands administered by the Bureau of Land management. The claims are owned by White Knight Gold (U.S.) Inc., a wholly owned subsidiary of White Knight Resources. The claims were originally staked between 1980 and 1994, by predecessors to White Knight. In March 1998, White Knight acquired a 100% interest in the New Pass claims from Quest USA Resources Inc. in consideration of US \$ 150,000 and a 2.75% NSR royalty. In March 2000, White Knight purchased the underlying 2.75% NSR by issuing 100,000 common shares.

There are no historic shafts, adits or prospect pits on the subject claims. All of the drill and access roads from exploration work conducted in the 1980's and 1990's have been reclaimed except for approximately 1500 feet. An existing Plan of Operation is on file with the Bureau of Land Management, and can be amended to accommodate

future exploration work. There are no known environmental liability issues on the New Pass property.

5.0 ACCESS, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE, AND PHYSIOGRAPHY

The property is easily accessed from Reno by following Interstate 80 east 30 miles to Fernley, and then east along Highway 50 through Fallon for 110 miles to the graded Edwards Valley Road. And then proceed 5 miles north to an unimproved road, and then 2.5 miles east south east to the center of the property. Numerous reclaimed drill roads exist on the property, many of which could be re-opened and utilized for future drilling.

The New Pass property is located on the western flank of the New Pass Range at elevations ranging from 5500 feet to 7000 feet above sea level. The climate is typical Basin and Range with hot summers with potential high temperatures of +100 degrees Fahrenheit and cold winters with potential low temperatures of -0 degrees Fahrenheit. Average annual rainfall amounts to between 10 to 15 inches. These climatic conditions allow work to be carried year round.

The vegetation found in the New Pass area is typical of Central Nevada and consists of sagebrush and other desert plants at the lower elevations. At the higher elevations, open stands of pinion pine and juniper occur mixed with the sagebrush.

No flowing water was observed on the property at the time of the visit. If there is water flow, it is likely to be seasonal only. However, wells for agricultural purposes are located in the valley just below the property within 2 miles. Water could be made available for mining purposes by filing for water rights or buying existing water rights.

If the property is put into production, additional mill site claims would need to be staked in order to support processing facilities, waste dumps, etc. These claims would likely be filed on the valley floor, just below the property. Proximity to the major supply center of Reno is a definite advantage in supporting any mining operations. The local population centers of Fallon (80 miles to the west) and Austin (36 miles to the east) would afford accommodations for the mining staff.

6.0 HISTORY

There were no obvious old, historic prospect pits, adits or shafts on the New Pass project area. Dekalb Mining first discovered gold on the New Pass Property in 1980 as a result of follow-up work to a NURE stream sediment survey. Dekalb transferred ownership of the claims it had staked to Northern Illinois Coal, Oil and Resources Mineral Ventures ("NICOR") in August of 1982. NICOR and its successor, Westmont Gold, Inc., explored the property from 1982 through 1992, and drilled a total of 165 reverse circulation drill holes.

Consolidated Ramrod Gold (USA), Inc. ("Ramrod") acquired New Pass in 1993. In 1995, Santa Fe Pacific Gold Corp. completed 11 reverse circulation drill holes on the

property under an exploration agreement with Ramrod. Ramrod was reorganized and renamed Quest USA Resources Inc. Quest sold the New Pass property to White Knight Gold (U.S.) Inc., a wholly owned subsidiary of White Knight Resources Ltd., in March 1998, in consideration of US \$ 150,000 and retained a 2.75% NSR royalty. In March 2000, White Knight purchased the underlying 2.75% NSR royalty by issuing 100,000 common shares.

In 1998, after White Knight purchased the property, White Knight completed 1:6000 scale mapping, collected 250 rock chip samples, prepared geochemical overlays for all surface rock chip data, and constructed 100 – foot cross sections with an Interdex mining software program. White Knight has incurred to date a total of US \$ 150,000 in exploration expenses. Overall exploration expenditures

Westmont Mining published an Indicated Resource for the New Pass project in 1989 (Wilkinson, et. al., 1989). Applying a 0.02 ounce per ton Au cutoff, Independent Mining Consultants of Tucson, Arizona calculated that the deposit contained 3.371 million tons that graded 0.042 oz/t Au, or a total of 142,000 contained ounces of gold.

7.0 GEOLOGICAL SETTING

The New Pass project is located within the Basin and Range physiographic province, on the western flank of the New Pass Range (Figures 2 & 3). The New Pass Range consists of a sequence of late Paleozoic and Triassic age metasedimentary, sedimentary and minor volcanic rocks. The Paleozoic sequence consists of chert, siliceous shale, siltstone sandstone, conglomerate and minor greenstones. The sequence is undated but the most likely correlation is thought to be with the Havallah sequence.

The Mesozoic sedimentary units are the most prevalent rocks in the immediate area of the New Pass property (Figure 4). A 1,000 to 2,000 foot thick sequence of an unnamed conglomerate forms the basal unit of the Triassic assemblage. The base appears to be a depositional disconformity and the top may be gradational into the Middle Triassic Favaret Formation consisting of siltstone and limestones. Overlying the Favaret is the Middle to late Triassic Augusta Mountain Formation. This formation has been subdivided into two members in this part of the New Pass Range: A lower transitional member consisting to thin to medium bedded carbonaceous limestone, and an upper member consisting of massive light gray limestone which forms bold outcrops which stand in prominent relief.

In the northern part of the claim block, the Augusta Mountain Formation is overlain by the Osobb and Cane Spring Formations. The lower Osobb Formation consists of thin bedded to laminated, silty limestone, while the upper Osobb is a medium to thick bedded, carbonaceous limestone. The Cane Spring Formation is a thick bedded to massive gray limestone.

To the west, and in fault contact with the Mesozoic rocks, is a sequence of Tertiary Volcanics. The Tertiary rocks are a series of pyroclastic units and flows, as well as some rhyolitic intrusives. In the westernmost part of the claim group, the Tertiary volcanics are covered by pediment gravels.

The mineralized jasperoid is developed along the fault bounding the Mesozoic calcareous rocks and the Tertiary volcanics. More specifically, the mineralized jasperoid is developed in the fault zone between the lower Augusta Mountain Formation and the Tertiary volcanics.

The Upper Paleozoic and Mesozoic rocks in the project area have been folded into a very large N70°W trending anticline that plunges about 40° to the west. North to north-east trending cross folds occur the Mesozoic section on a more limited scale.

8.0 DEPOSIT TYPES

The mineralization at New Pass occurs within a jasperoid, developed in a de-calcified limestone. The first event was thought to be de-calcification followed by the silicification which produced the jasperoid. These events were controlled by the range front fault, along which the hydrothermal fluids passed. These fluids also commuted along faults and fault breccia zones that cut through the Triassic sequence east of the range front faults. Alteration of this type can be found up to 4,000 feet from the main jasperoid along the range front faults.

The passage of the hydrothermal fluids caused the argillization and bleaching of the rocks surrounding the New Pass jasperoid. The argillization and bleaching occurs in both the sedimentary sequence and in the Tertiary volcanics. Silicification of the felsic tuffs also occurred and was observed in the field. In addition, zones of significant sulfide concentrations ranging from less than 1% to more than 10% by volume have been noted in the drill logs.

This deposit is a sediment hosted gold deposit. In many ways it is similar to deposits found elsewhere in Nevada. Geological similarities between the New Pass area and the McCoy – Cove area have been noted by Hughes (1998). At present, the principal mineralization host is the jasperoid, but evidence exists that portions of the de-calcified limestones and the tuffaceous volcanics also contain highly anomalous gold values

Paster (1989) noted in a petrographic study on a total of 24 samples of the jasperoid that trace amounts of anatase and rutile were present in all of the samples and that the presence of these mineral is synonymous with epithermal precious metal deposition. He also added that the alteration indicated a very low temperature/pressure hydrothermal system which is in primarily in the argillic zone.

9.0 MINERALIZATION

The mineralization on the New Pass property is controlled by hydrothermal fluids moving along fault and breccia zones. Both range front faults and cross faults as well as other permeable zones have been utilized by these hydrothermal fluids.

The first event was likely the de-calcification of the limestone along the range front fault. Concurrent with this, argillization of other parts of the limestone as well as the volcanics, especially the tuffaceous units, occurred. The de-calcification of the limestone increased the permeability of the rocks allowing an influx of hydrothermal fluids. This quickly provided the silica that preserved some original sedimentary structures as well as some fossils. Although the main jasperoid resulted from subsequent silicification of de-calcified limestone, not all de-calcified rock has been re-silicified.

Complete silicification resulted in the formation of the main jasperoid, which extends for at least 3,000 feet along strike and at least 1500 feet down dip, based on drill hole intercepts (Figure 6). Thicknesses of the jasperoid range from about 20 feet to over 200 feet near the surface. The main jasperoid shows evidence for multiple stages of silicification (Hughes, 1998):

- 1.) Early, pervasive fine grained silica
- 2.) Thin dark colored quartz microveinlets frequently containing fine pyrite
- 3.) Overgrowths of fine grained quartz enclosing breccia fragments
- 4.) White, translucent chalcedonic quartz veinlets and coatings devoid of sulfides

Silicification as well as argillization, occurs in both the footwall calcareous sedimentary rocks and the hanging wall volcanics, especially within the tuffaceous units. Highly anomalous gold values have been noted in some drill hole intercepts in these areas, as well as in some of the de-calcified but un-silicified rocks.

The distribution of significant gold mineralization in the main jasperoid deposit is displayed by grade – thickness plots for the drill holes (Figure 5). The highest gold grades within the two “pods” appear to be associated with jasperoid intervals containing: intense brecciation; abundant quartz veining, higher pyrite concentrations; and by a carbonaceous content. However, the drill hole information did not establish any clear relationship between sulfide concentrations and gold values.

A petrographic study was completed by Paster (1989) on 22 jasperoid samples from drill holes and from 2 surface slabs. The predominant gold occurrence was found to be ~1 micron particles pervasively dispersed in silicified limestone, usually occurring along chert grain boundaries. Pyrite and arsenopyrite, also ~1 micron in size, were also found pervasively throughout the chert. The gold did not appear to be related to any particular limestone or sediment type. Gold 3 to 10 microns in size was also sometimes found in quartz veins and veinlets. No visible characteristics of the gold-bearing and non-gold-bearing veins or breccias were found that could distinguish the two types in hand specimen.

10.0 EXPLORATION

Consolidated Odyssey Explorations has not yet conducted any exploration work on the New Pass property.

NICOR and its successor, Westmont Gold, Inc., explored the property from 1982 through 1992, and drilled a total of 165 reverse circulation drill holes. Consolidated Ramrod Gold (USA), Inc. ("Ramrod") acquired New Pass in 1993. In 1995, Santa Fe Pacific Gold Corp. completed 11 reverse circulation drill holes on the property under an exploration agreement with Ramrod. In 1998, after White Knight purchased the property, White Knight completed 1:6000 scale mapping, collected 250 rock chip samples, prepared geochemical overlays for all surface rock chip data, and constructed 100 – foot cross sections with an Interdex mining software program.

To date, a total of 936 rock chip samples have been taken from the New Pass property and in aggregate average 204 ppb gold. Of these samples, 35 rock chip samples contained greater than 1 ppm gold, averaging in aggregate 2.43 ppm gold or 0.07 oz/ton Au. Nearly all of these higher grade rock chip samples came from one of three areas: 1) the main jasperoid, with the drill defined higher grade pods, 2) leakage along the range front fault and in road cuts to the northwest of the main jasperoid and 3) leakage along the upper contact of a more permeable silty limestone unit found below a massive limestone north of the main jasperoid (Cavanaugh and Warren, 1999).

Westmont Gold completed extensive geochemical studies on the New Pass property. The geochemical studies involved surface rock chip samples, drill hole samples, soils, and biogeochemical studies. These studies were used to identify satellite areas that warranted exploration drilling. These studies were also used to describe the geochemical nature of the gold bearing jasperoid. One of the principal conclusions of these studies was that there was likely a two-fluid mineralizing process involved with the formation of the gold enriched jasperoid. In addition, Mo was found to be a component of both fluids. This in turn suggested that the hydrothermal fluids responsible for the gold mineralization may be related to an intrusive at depth.

11.0 DRILLING

Consolidated Odyssey Explorations has not yet conducted any drilling on the New Pass property. However, NICOR and its successor, Westmont Gold, Inc., explored the property from 1982 through 1992, and completed a total of 165 drill holes. Of that total, 110 drill holes have been located in the main jasperoid zone and all but 11 of the drill holes were vertical.

In 1995, Santa Fe Pacific Gold Corp. completed 11 reverse circulation drill holes on the property under an exploration agreement with Ramrod. These holes were vertical, between 840 feet and 1000 feet in depth and were located to the west of the main jasperoid to test its down dip extension. Only 3 of these drill holes intercepted the jasperoid. One of these, drill hole DNE-2, is shown on cross section B-B' in Figure 6. The drill holes that did not intercept the jasperoid were located further west.

A summary of the significant gold intercepts in the drill holes completed on the New Pass project are given in Appendix III. A generalized drill hole location map is presented in Figure 5. Also depicted in Figure 5, are the "pods" of higher grade mineralization and the location of the two cross sections shown in Figure 6.

In Figure 6, the envelope of mineralization is shown in red. The mineralization is entirely within the jasperoid and as such, the envelope shown is essentially a map of the jasperoid. The colored histograms shown along the drill holes within the mineralization envelope are obviously meant to relate the gold value for that interval, but no scale or explanation has been found in the files, nor are digital copies of the cross sections available. The sections have been included here in order to show the geometry of the main jasperoid.

12.0 SAMPLING METHOD AND APPROACH

During the recent visit to the New Pass property a total of 9 samples (Nos. 198859 through 198867) were taken from various locations on the property by the author. All samples were placed into a sample bag and sealed and subsequently delivered to the BSI Inspectorate analytical laboratory in Sparks, Nevada. Sample Nos. 198859 through 198861 were from various locations in the main jasperoid zone. Sample No. 198862 was taken in the de-calcified limestone immediately beneath the jasperoid. Sample No. 198863 is from a silicified tuff about 1000 feet north of the main jasperoid and sample Nos. 198864 through 198867 were taken from a road cut along a reclaimed drill road about 2500 feet north of the main jasperoid zone. Sample descriptions and laboratory results are presented in Appendix II.

13.0 SAMPLE PREPARATION ANALYSIS AND SECURITY

The samples were delivered to BSI Inspectorate Laboratories located in Sparks, Nevada by the author. The samples were then thoroughly dried, and the crushed to >80% -10 mesh using a two stage crushing process, jaw and roll mill. A 300 gram split is then obtained using a Jones riffle splitter and reduced to >90% -150 mesh. Clean sand is used to clean the pulverizer between all samples.

Gold determinations are made using fire assay with a gravimetric or Atomic Absorption finish. Trace element determinations are made using optimal acid digestions followed by Atomic Absorption Spectroscopy and Inductive Coupled Plasma. A minimum fifteen percent of all analyses performed are directly run for quality control. Every tenth sample is repeated and for every 20 samples run, a standard or blank is also analyzed. For gold determinations, a total of 9 certified gold standards purchased through 2 separate manufacturers (Rocklabs and CDN Resources) are implemented into our fire assay Quality Control program for gold analyses finished with both gravimetric and AAS methods.

BSI Inspectorate is ISO 9000 certified ABS Quality Evaluations, Inc. annually and the Quality Assurance Program meets all the established criteria as related to disclosure requirements for trading mining and exploration companies under NI-43-101.

14.0 DATA VERIFICATION

Geological information for the New Pass property has been compiled from available private and public sources.

In conjunction with the data and property review of the New Pass property, the author collected 9 samples of rock from outcrop on the property. Two of the samples returned greater than 1 ppm gold (198861 – 1.733 ppm Au and 198866 – 3.561 ppm Au) as well as elevated concentrations of pathfinder elements. These values are within the range of values reported from previous workers. This data is presented in Appendix II.

15.0 ADJACENT PROPERTIES

The historic New Pass Mining District lies about 2 miles south east of the subject New Pass claim group. Gold was discovered in the New Pass District about 1864. A number of shafts and adits were developed in the district. The deepest shaft is the Thomas W. shaft at 550 feet. A total of several miles of underground workings were developed in the district. The total production from the New Pass District is estimated to be about 35,000 tons of ore that averaged a little less than one ounce of gold and silver per ton (Stewart, et.al., 1977).

The gold deposits of the New Pass District are developed within the Paleozoic rocks, which lie stratigraphically beneath the Augusta Mountain formation, which is the host of the mineralization on the New Pass Claim Group. The New Pass District gold deposits are steeply dipping quartz veins, striking north or northwest and dipping steeply east or west. The ore shoots vary from less than 1 foot to as much as 10 feet in thickness. The ore consists of free gold with minor amounts of silver and some lead and copper sulfides, carbonates and oxides (Stewart, et.al., 1977).

A total of 10 unpatented lode mining claims are located about 1 mile northeast of the subject claim group. The claims are held by individuals from Austin, Nevada. Nothing more is known about these claims.

16.0 MINERAL PROCESSING AND METALLURGICAL TESTING

Consolidated Odyssey Explorations has not conducted any metallurgical testing on any material from the New Pass Property.

However in 1988, Westmont Gold submitted 6 samples composited from drill cuttings to McClelland Labs in Sparks, Nevada for preliminary metallurgical testing. The test included bottle rolls (as received and at 100 mesh) and shake tests. Samples submitted included oxidized, reduced and mixed ore types. Samples generally consisted of jasperoid, however minor amounts of siltstone were included.

The results indicated that the recoveries for reduced, carbonaceous and pyritic jasperoid are between 5% and 33%, and consequently this material may not be amenable to heap leaching. The oxidized jasperoid demonstrated good recoveries – between 75% and 77%.

17.0 MINERAL RESOURCE ESTIMATES

Consolidated Odyssey Explorations has not performed any ore resource calculations on the New Pass Property.

In 1988 and 1989, Westmont Gold retained Independent Mining Consultants of Tucson, Arizona to perform a computer based ore reserve calculation. Approximately 110 drill holes had been located within the main jasperoid zone (Figure 5), and the calculation was based on data from these drill holes. The results of this exercise gave a combined total for all material types of 3.371 million tons grading 0.042 ounces per ton Au, or a total of 142,000 contained ounces, after applying a cutoff of 0.02 ounces per ton Au. The oxide content of this total is 2.1 million tons, grading 0.044 ounces per ton, or a total of 92,400 contained ounces, with a recovery of 75 – 77%.

These numbers have been referred to in the various internal reports and memos as: “Reserves”, “Geological Reserves”, “Geological Resources” and “Resources”. However, after examining the available data, including drill logs, assay logs, drill hole locations and density, metallurgical work completed and the nature of the mineralization and then applying the principles outlined in the “Australasian Code for Reporting of Mineral Resources and Ore Reserves” (The JORC Code) to this data, the term that is most appropriate for this deposit is “Indicated Mineral Resource” or simply “Indicated Resource”.

18.0 INTERPRETATION AND CONCLUSIONS

The New Pass property consists of 107 unpatented lode mining claims on the west flank of the New Pass Range in eastern Churchill County, Nevada. Surface mapping along the western margin of the New Pass Range has identified a zone of range front structures. The main jasperoid is localized by a range front fault separating Triassic calcareous sedimentary rocks from Tertiary volcanics. Receptive limestones and silty limestones in the Triassic Augusta Mountain Formation have been pervasively replaced by silica from hydrothermal fluids that also deposited gold.

The hydrothermally altered rocks extend for more than 3,000 feet both north and south of the main jasperoid along the range front structures. Alteration also extends up to 2,500 feet into the Augusta Mountain Formation, apparently localized along cross faults. Any extension to the west of the range front fault is buried beneath the pediment gravels.

Since the property’s discovery in 1980, over US\$1.5 million has been expended on exploration and development work. The exploration work identified the main jasperoid zone as well as several satellite targets. This work included surface rock chip sampling, soil sampling, geologic mapping, and extensive geochemical analyses. A total of 165 drill holes have been completed, with approximately 110 of these drill holes located within the main jasperoid zone. The Indicated Resource identified by Westmont Gold in 1988 – 1989 is located within the main jasperoid.

The satellite targets are located along the main range front fault as well as being localized along cross faults. Some of these targets have been drilled with mixed results. A number of these targets remain untested. In addition to the satellite targets, the overlying Tertiary volcanics as well as areas of de-calcified limestone in the footwall have not been adequately tested in the area of the main jasperoid.

The work completed to date indicates the presence of an epithermal system in which the hydrothermally altered rocks extend for at least 2.5 miles along the range front fault/structural system and about 0.5 miles eastward into the Triassic calcareous rocks. An Indicated Resource has been developed within the main jasperoid body. Satellite target areas have been found and some of them have been drilled. Also, northeast trending cross faults are known immediately to the north and immediately to the south of the main jasperoid body. Other high angle faults have been observed to cut the main jasperoid itself. All of these areas have not yet been adequately tested, and are attractive targets having the potential to increase the resource base. In addition, a possible intrusive lies at depth beneath exposed mineralization, which also presents an attractive drilling target

19.0 RECOMMENDATIONS AND BUDGET

It is recommended that a first year exploration budget of US\$ 250,000.00 be expended. These funds should be allocated in two exploration phases.

The recommended Phase I program includes: digital recompilation of all of the existing data; re-plotting and reinterpretation; detailed geologic mapping, especially within the main jasperoid in order to identify internal structural controls on the mineralization; and geophysical surveys. The geophysical surveys should include an Air Magnetometer survey; test Induced Polarization - Resistivity lines, and the initiation of a gravity survey.

The entire New Pass Property should be flown in the Air Magnetometer survey, while the Induced Polarization – Resistivity and gravity surveys will be conducted as more localized tests to confirm the process and the results before expanding the surveys. All of this work will be performed on a contract basis by Geophysical Consultants.

Upon the successful completion of Phase I, the Phase II program would begin. The Phase II program should consist of both reverse circulation and core drilling. The initial target should be the main jasperoid in order to confirm the grades previously reported and to test high angle structures, both the northeasterly trending structures which bound the jasperoid to the north and south, and internal high angle structures identified in Phase I.

PHASE I BUDGET

- Digital recompilation, re-plotting and reinterpretation of data
1 geologist, 1 technician (30 days @ US \$750.00/day) 22,500
- Geological mapping
1 geologist, 1 technician (30 days @ US \$600.00/day) 18,000
- Air Magnetometer Survey (Maximum) 20,000
- Induced Polarization – Resistivity (Test Lines) 9,500
- Gravity Survey 8,000
- Phase I Total US \$ 78,000**

PHASE II BUDGET

- Reverse Circulation Drilling
5000 feet at US \$13.50/foot 67,000
- Diamond Core Drilling (NQ Size)
2000 feet at US \$ 37.50/foot 75,000
- Sub Total 142,000
- Management, Supervision and Logistics 8,000
- Contingencies Phase II (15%) 22,500
- Phase II Total US \$ 172,500**

TOTAL FIRST YEAR BUDGET US \$ 250,500

Sincerely

Paul A. Pelke, California Registered Geologist No. 4150
November 8, 2004

21.0 STATEMENT OF QUALIFICATIONS

Paul A. Pelke
California Registered Geologist, No. 4150
3033 Cashill Blvd.
Reno, Nevada 89509

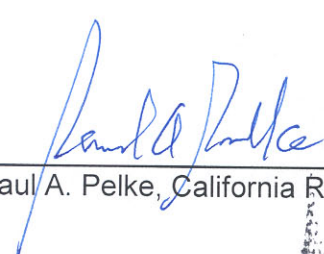

I, Paul A. Pelke, SB, SM, California Registered Geologist No. 4150 do hereby certify that:

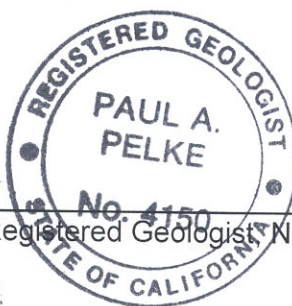

- 1) I maintain a geological consulting practice at 3033 Cashill Blvd., Reno, Nevada, USA.
- 2) I am a graduate of The Massachusetts Institute of Technology in 1971 with Bachelor of Science and Master of Science degrees in Geology and Geochemistry, from the department of Earth and Planetary Sciences.
- 3) I am a registered professional geologist: California Registered Geologist, No. 4150, and as such I am qualified to contribute to the accompanying report.
- 4) I have worked as a geologist for the past 32 years.
- 5) I have read the definition of "Qualified Person" as set out in National Instrument 43-101 ("NI 43-101") and certify that by reason of my education, affiliation with a professional association and past relevant work experience that I fulfill the requirements to be a "Qualified Person" for the purposes of NI 43-101.
- 6) I am responsible only for the recent sampling data that I obtained on October 12th, 2004. The sources of all information are quoted in the report. The information provided by the various parties is to the best of my knowledge and experience correct and accurate.
- 7) Neither I nor any affiliated entity of mine own, directly or indirectly, any interest in the securities of Consolidated Odyssey Explorations, White Knight Resources or any associated or affiliated companies or in the subject properties described in this report.

- 8) As of the date of this Certificate, I am not aware of any material fact or material change with respect to the subject property that would make the report misleading.
- 9) Neither I nor any affiliated entity of mine, have earned the majority of our income during the preceding three years from Consolidated Odyssey Explorations, White Knight Resources or any affiliated companies.
- 10) I have read National Instrument 43-101 and Form 43-101F1 and have prepared my part of the report with this NI 43-101 with generally accepted Canadian Industry Practice
- 11) I consent to the Filing of the Technical Report with any Stock Exchange and other Regulatory Authority and the publication by them, including electronic publication in the public company files on their websites accessible to the public, of the Technical Report.

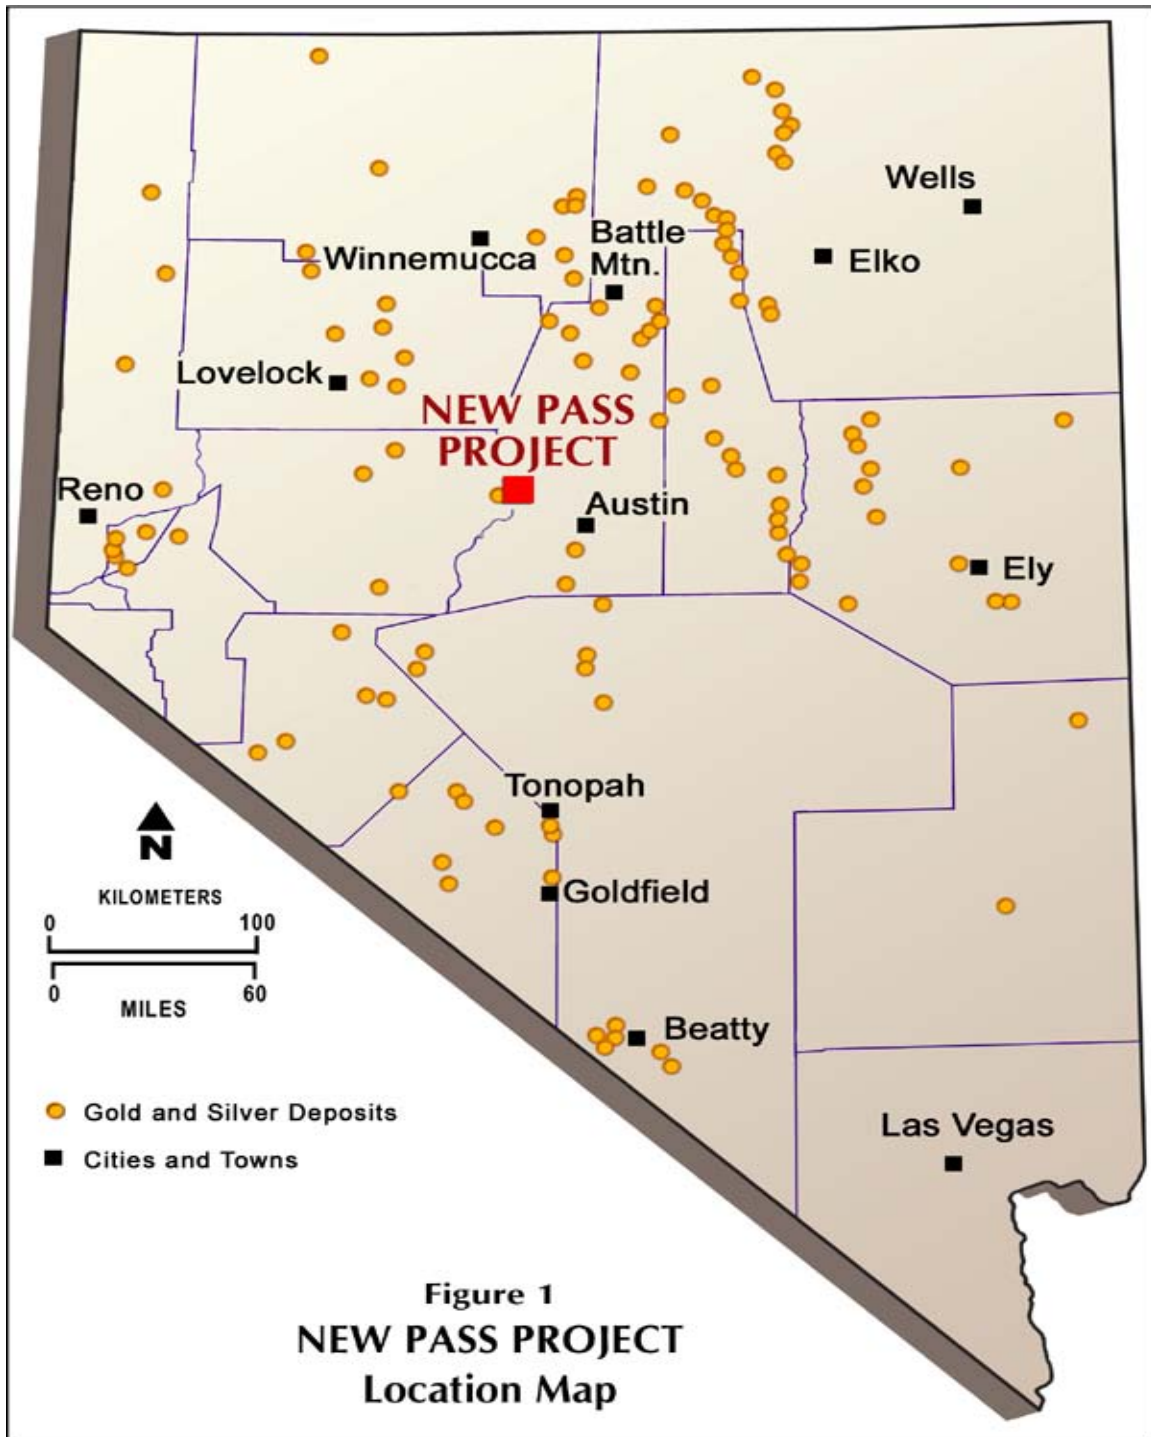

Dated at Reno, Nevada this 8th day of November, 2004

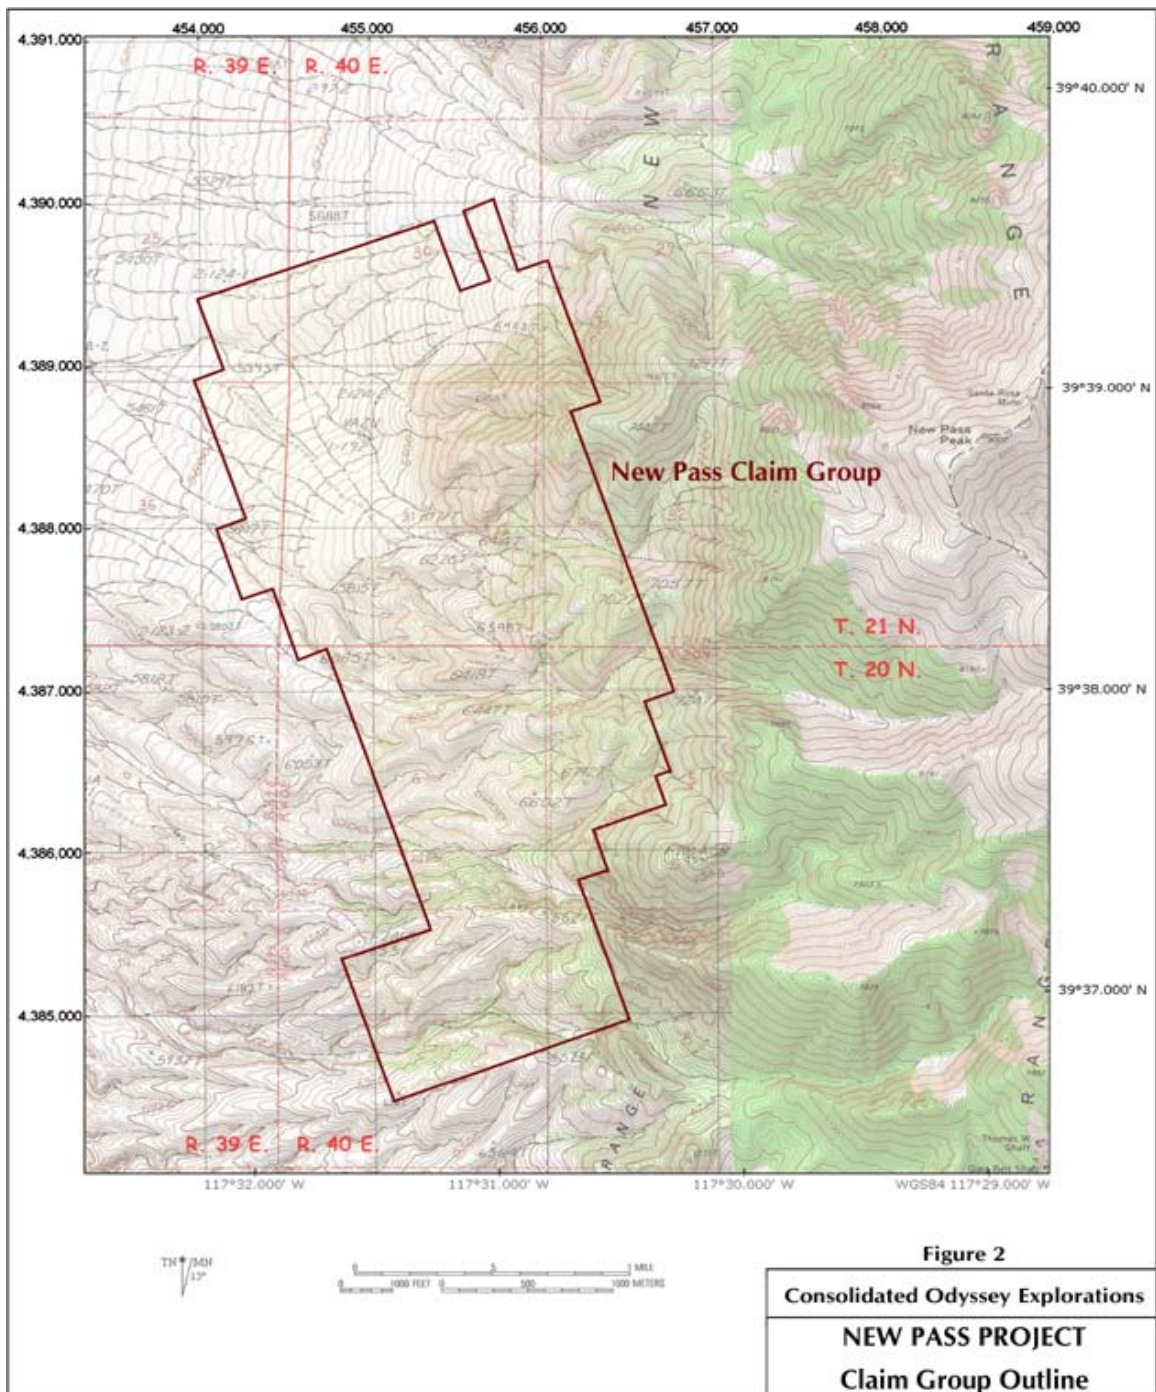

Signature of Qualified Person:

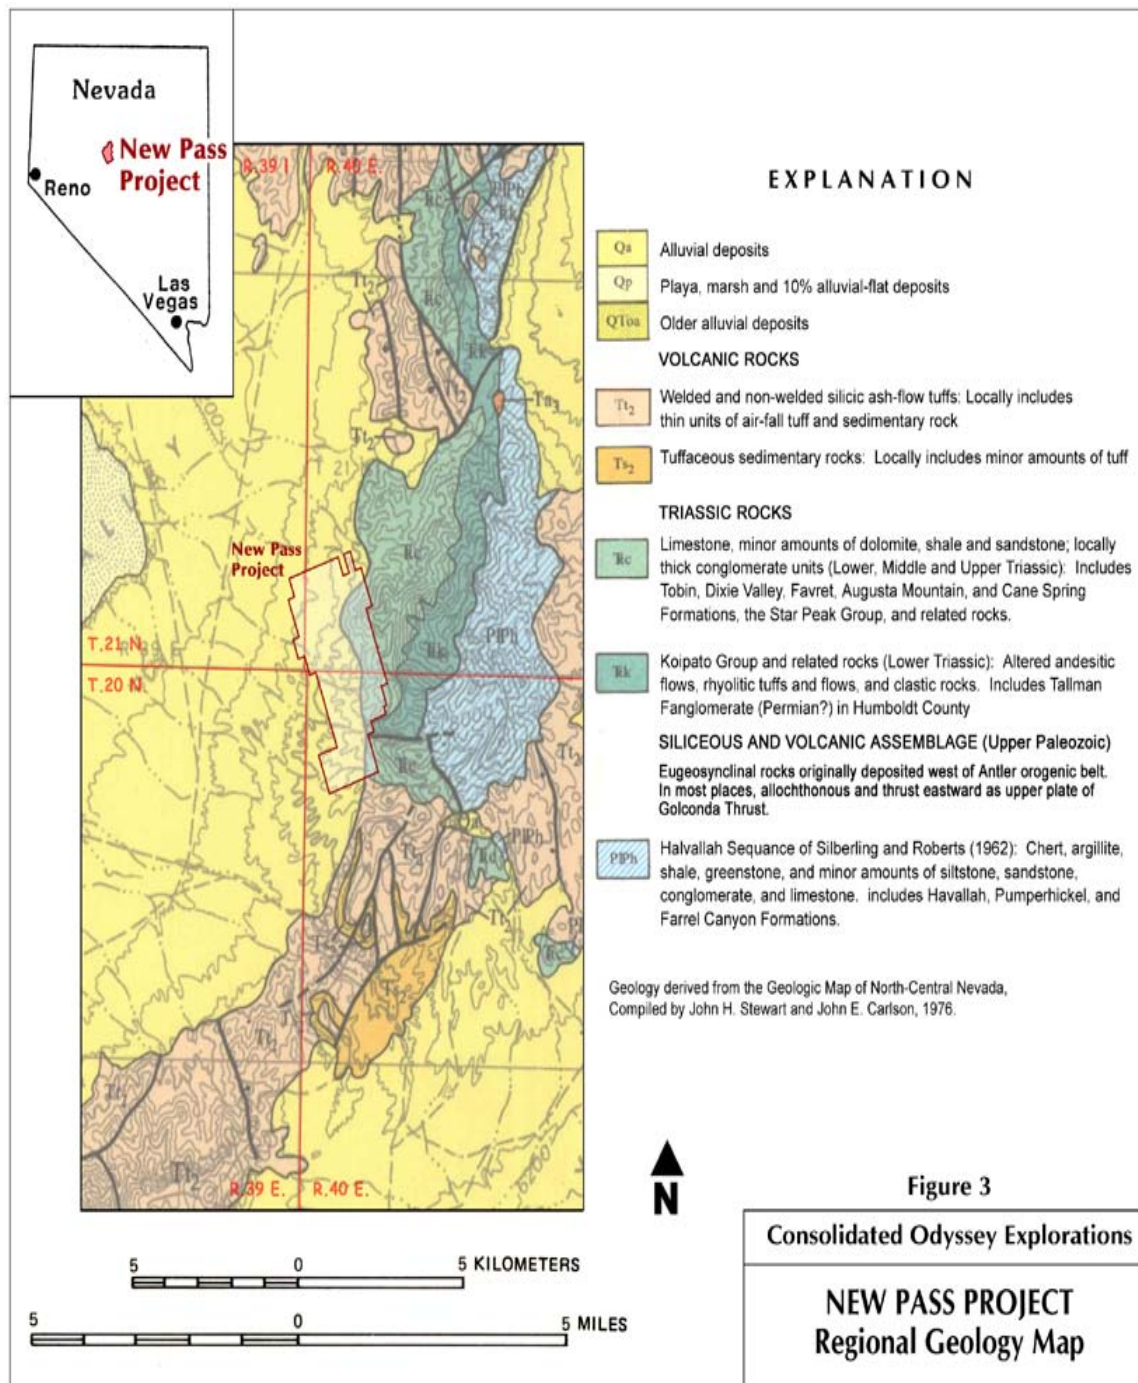

Paul A. Pelke, California Registered Geologist No. 4150
